Soil Survey of Essex County, New York

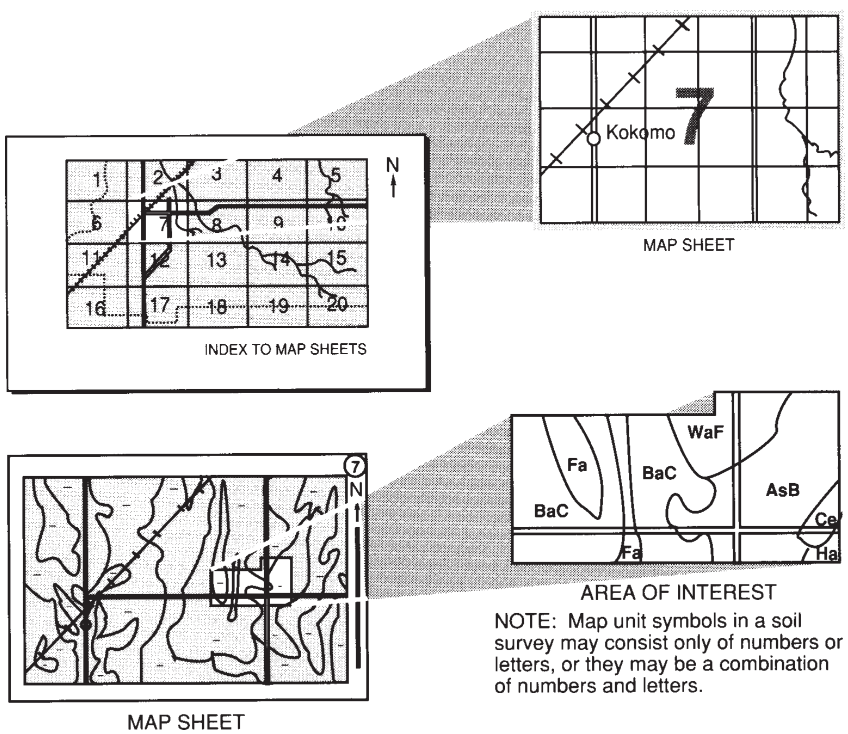
How To Use This Soil Survey

The detailed soil maps can be useful in planning the use and management of small areas.

To find information about your area of interest, locate that area on the **Index to Map Sheets**. Note the number of the map sheet and turn to that sheet.

Locate your area of interest on the map sheet. Note the map unit symbols that are in that area. Turn to the **Contents**, which lists the map units by symbol and name and shows the page where each map unit is described.

The **Contents** shows which table has data on a specific land use for each detailed soil map unit. Also see the **Contents** for sections of this publication that may address your specific needs.



NOTE: Map unit symbols in a soil survey may consist only of numbers or letters, or they may be a combination of numbers and letters.

This soil survey is a publication of the National Cooperative Soil Survey, a joint effort of the United States Department of Agriculture and other Federal agencies, State agencies including the Agricultural Experiment Stations, and local agencies. The Natural Resources Conservation Service (formerly the Soil Conservation Service) has leadership for the Federal part of the National Cooperative Soil Survey.

Major fieldwork for this soil survey was completed in 1999. Soil names and descriptions were approved in 2007. Unless otherwise indicated, statements in this publication refer to conditions in the survey area in 1999. This survey was made cooperatively by the Natural Resources Conservation Service and the Cornell University Agricultural Experiment Station. The survey is part of the technical assistance furnished to the Essex County Soil and Water Conservation District. Partial funding for this survey was provided by the Essex County Soil and Water Conservation District and by the New York State Department of Agriculture and Markets.

Cover: View of Lake Placid from the summit of Whiteface Mountain looking southwest. In the foreground where slopes are covered with Red Spruce and Balsam Fir, the Ricker, Couchsachraga, Skylight, and Santanoni soils, and common rock outcrops dominate. On the mid-slopes, which have a mix of hardwoods and conifers, Mundalite, Rawsonville, and Hogback soils dominate. On the lower slopes around the lake, Becket, Tunbridge, and Lyman soils are common. On the low hilly areas and terraces in the village at the south end of the lake, Monadnock and Adams soils dominate. The western High Peaks Region including the Sawtooth, Nye, and Street mountains are in the background.

Additional information about the Nation's natural resources is available online from the Natural Resources Conservation Service at http://www.nrcs.usda.gov.

Issued 2010

Foreword

This soil survey contains information that affects land use planning in this survey area. It contains predictions of soil behavior for selected land uses. The survey also highlights soil limitations, improvements needed to overcome the limitations, and the impact of selected land uses on the environment.

This soil survey is designed for many different users. Farmers, ranchers, foresters, and agronomists can use it to evaluate the potential of the soil and the management needed for maximum food and fiber production. Planners, community officials, engineers, developers, builders, and home buyers can use the survey to plan land use, select sites for construction, and identify special practices needed to ensure proper performance. Conservationists, teachers, students, and specialists in recreation, wildlife management, waste disposal, and pollution control can use the survey to help them understand, protect, and enhance the environment.

Various land use regulations of Federal, State, and local governments may impose special restrictions on land use or land treatment. The information in this report is intended to identify soil properties that are used in making various land use or land treatment decisions. Statements made in this report are intended to help the land users identify and reduce the effects of soil limitations on various land uses. The landowner or user is responsible for identifying and complying with existing laws and regulations.

Great differences in soil properties can occur within short distances. Some soils are seasonally wet or subject to flooding. Some are shallow to bedrock. Some are too unstable to be used as a foundation for buildings or roads. Clayey or wet soils are poorly suited to use as septic tank absorption fields. A high water table makes a soil poorly suited to basements or underground installations.

These and many other soil properties that affect land use are described in this soil survey. The location of each soil is shown on the detailed soil maps. Each soil in the survey area is described. Information on specific uses is given for each soil. Help in using this publication and additional information are available at the local office of the Natural Resources Conservation Service or the Cooperative Extension Service.

Soil Survey of Essex County, New York

By Gerald W. Smith, Natural Resources Conservation Service

Fieldwork by Steven C. Carlisle, Shawn M. Finn, Dale S. Gates, Matthew W. Havens, Steven S. Indrick, Paul E. Konopka, Val J. Krawiecki, Stephen J. Page, Stefan T. Seifried, Mark H. Silverman, Gerald W. Smith, Edward R. Stein, Theodore D. Trevail, Natural Resources Conservation Service, and Brian F. Grisi, New York State Adirondack Park Agency

United States Department of Agriculture, Natural Resources Conservation Service, in cooperation with Cornell University Agricultural Experiment Station

Essex County lies on the western shore of Lake Champlain in the northeastern part of New York State (fig. 1). The county is bounded on the north by Clinton County; on the south by Warren and Washington Counties; and on the west by Franklin and Hamilton Counties.

The county is mainly rural. It covers an area of 1,225,900 acres, or about 1,915 square miles (USDA Natural Resources Conservation Service, 2002). About 69,700 acres is census water. Elevations range from 95 feet at Lake Champlain (mean lake level) to 5,344 feet at the summit of Mount Marcy. Elizabethtown is the county seat and is situated in the eastern foothills area between the Adirondack High Peaks Region on the west, and the Champlain Valley on the east.

General Nature of the County

In 2000, the county had a population of about 38,851 and has more or less steadily grown since 1900 when the population was approximately 31,000 (US Census Bureau, 2000). About two thirds of the population resides within the hamlets and villages of the county.

Tourism and hospitality, forest products, mining, and agriculture are some of the more important industries in the county. Agriculture, at one time the most important industry in the county, has declined steadily since 1900 when total farms and land in farms was 2,274 farms with 359,008 total acres in farms, as compared to 2002 values of 236 farms with 55,022 total acres in farms, or roughly 5 percent of the county (US Census of Agriculture, 2002). Nearly half of sales from farms in the county were involved with production of dairy products. Other farm production includes hay and other crops, vegetables, orchards, nursery and greenhouse, and other miscellaneous products. Mining has also declined steadily since it began with European settlement, but NYCO Minerals still operates wollastonite mines in Lewis and Willsboro. Essex County is 92 percent forested, and of this, approximately 50 percent is private commercial forestland, and the remainder is Adirondack Forest Preserve (Craul, 1987). Several large industrial forestry firms still manage timberland in the county, and International Paper Company operates a paper mill in Ticonderoga. The Adirondack High Peaks Region, part of the Adirondack Forest Preserve, lies almost entirely within

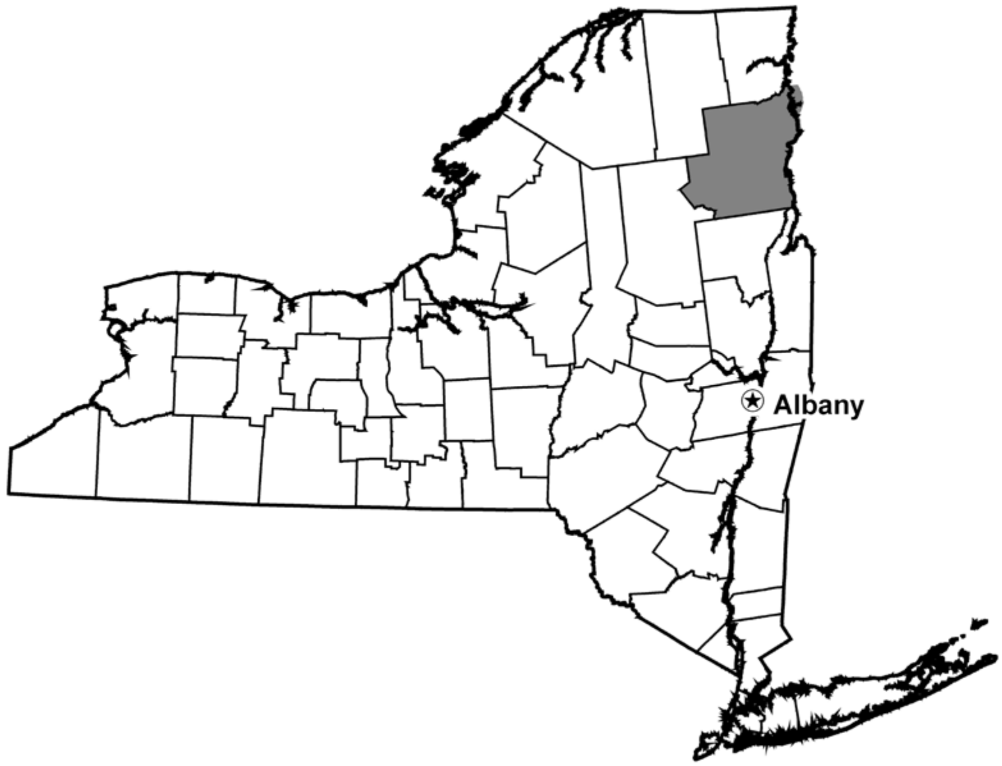

Figure 1.—Location of Essex County in New York.

Essex County and draws thousands of hikers, backpackers, skiers, artists, and others annually for a rich outdoor recreational experience. Other parts of the Forest Preserve contain nearly 80,000 acres of lakes, ponds, and rivers and offer excellent recreational fishing and hunting opportunities. The Village of Lake Placid, host of the 1932 and 1980 Winter Olympic Games, located just north of the Adirondack High Peaks Region is a popular four season resort area and host to thousands of visitors from around the world annually.

History and Development

The earliest inhabitants of the area we now know as Essex County were Paleoindians who migrated here shortly after deglaciation of the Champlain Valley about 11,300 years before present (BP). They were semi-nomadic, hunter-gatherers who presumably followed caribou, woolly mammoth, and other Pleistocene mega-fauna as they exploited the new periglacial, tundra-like grasslands. They camped along the shores of the “Champlain Sea”, an estuary of the Atlantic Ocean, which occupied the valley for a time after the ice sheet retreated north of the St. Lawrence River. This period of habitation lasted from approximately 11,300 to 9,000 years BP. Later habitation occurred during what is known as the Archaic Period between 9,000 and 2,900 years BP. This period is characterized by a warmer climate and a transition from grassland tundra to forested ecosystems, extinction of the mega-fauna, and migration north of other tundra dependant game species like the caribou. These people had to adapt to the new environment and new game species, and were also hunter-gatherers and fishermen, but evidence suggests they were less nomadic and established more permanent settlements along major streams and rivers entering the valley. The final pre-European period of habitation is known as the Woodland Period lasting from about 2,900 to 400 years BP. This period is characterized by establishment of

substantial settlements along flood plains of major streams and rivers as they entered the lake, and technological advancements such as agriculture, pottery, and metal tools. Subsistence patterns gradually changed to a mix of hunting, fishing, gathering, and early agriculture, leading to a more sedentary lifestyle. During this period, the development of familiar Native American cultures such as the Iroquois occurred. As the Woodland Period progressed, Lake Champlain became a boundary between the Iroquois people to the west, and the Western Abenaki people to the east. By the end of the Woodland Period, the Champlain Valley was home to the St. Lawrence Iroquois, the Western Abenaki, the Mahican, and the Mohawk peoples (Lake Champlain Maritime Museum, 2009). There is also evidence that late in the Woodland Period, the region was a contested area between the Five Nations Iroquois of central New York and Algonquin of the St. Lawrence and Ottawa River Valleys over access to hunting and fishing grounds. This conflict persisted into the time of European settlement over competition for the fur trade.

European contact in the area began with the French explorer Jacques Cartier in 1534, when he entered the mouth of the St. Lawrence River looking for the Northwest Passage. Cartier attempted colonization of the St. Lawrence Valley and laid the groundwork for the northern fur trade at this time. In July 1609, French explorer Samuel de Champlain, also seeking to develop the fur trade, entered the Champlain Valley and was the first European to see the lake that now bears his name, claiming the region for France (Lake Champlain Maritime Museum, 2009). With two of his men and a war party of Algonquin, Huron, and Montagnais peoples, they confronted and defeated a group of Mohawk Iroquois warriors at Ticonderoga, thus setting the tone for continued conflict in the region for the next two centuries. The discovery of a nearly complete water route from the St. Lawrence to the Hudson River was of great importance to the Europeans. The Dutch, led by explorer Henry Hudson, had claimed the lands north of Albany up into the Champlain Valley. Although both colonial powers never initially settled the land in the Champlain Valley, they were very interested in its resources, heavily involved in the fur trade, and dependant on the Native Americans in the valley to supply them with furs. During the first half of the seventeenth century, the Champlain Valley was a staging area for Mohawk Iroquois to launch raids on Native American and French settlements in the St. Lawrence Valley. Additional conflicts between the Mohawks and the Western Abenaki and Mahicans added to the instability of the region.

By 1664, the British had captured the colony of New Amsterdam (New York City), and had assumed all claims to territory held by the Dutch north of Albany, including the Champlain Valley. At this time, and continuing for the next one hundred years, the British with the aid of their Iroquois allies, battled the French and their Native American allies over control of the Champlain Valley and its environs. The French held control of the valley for most of this period establishing forts at Isle La Motte (Quebec) in 1666, Crown Point in 1690 (Fort St. Frederic), and at Ticonderoga in 1755 (Fort Carillon). Early on, conflicts mainly concerned the French defending against the British backed Iroquois who had been harassing them for some time. Later hostilities mirrored conflicts in Europe with no less than four wars occurring on some level in the region, ending with the French and Indian War from 1754 to 1763. In 1759, the British defeated the French at Fort Carillon, and by the following year had completely driven the French out of the valley (Lake Champlain Maritime Museum, 2009).

Very little European settlement had occurred prior to 1763, except adjacent to the forts, because of the turmoil. The first important settlement of Essex County was established by William Gilliland at the mouth of the Boquet River at Willsboro in 1765. Gilliland had acquired several thousand acres between the Boquet and Split Rock in Essex, and engaged tenants to clear the land for farming, and establish industries along the river. A similar settlement was being established by Samuel Deall along the La Chute River at Ticonderoga around the same time. Other early settlers were former

soldiers who had served in the valley during the wars and were granted land in return for their service (Smith, 1885).

This short period of stability was disrupted by the Revolutionary War (1775–1783), brought on by the European colonists' dissatisfaction with British rule. Increasing unrest by colonists from unreasonable taxes and general limitations of rights, eventually led to the battles of Lexington and Concord, Massachusetts on April 19 1775, and the start of the Revolution. Within a few weeks of these battles, Ethan Allen and Benedict Arnold attacked and captured Forts Ticonderoga and Crown Point in order to retrieve the British cannon for siege, and drive the British out of Boston. As a result of the battles at Ticonderoga, Crown Point, and St. Johns (Quebec), the Americans captured a number of warships and held control of the lake well into 1776. Throughout the year, the British and Americans built up their fleets in preparation for the Battle of Lake Champlain which took place off Valcour Island on October 11, 1776 with Benedict Arnold commanding the American fleet. The outgunned Americans were eventually driven back to Fort Ticonderoga after losing many ships, and the British now assumed control of the lake. The Americans worked to strengthen Fort Ticonderoga and Mount Independence in Vermont after the lake battle, but were driven out of both forts in July 1777 after the British hauled a cannon up the undefended Mount Defiance just south of Ticonderoga, and presented an insurmountable threat to the American forts. The British held control of the lake until the end of the war in 1783, and used it as a staging area to launch raids into the Hudson and Mohawk valleys for the remainder of the conflict (Lake Champlain Maritime Museum, 2009). Many settlements loyal to the Americans were abandoned and destroyed after the British regained control of the lake, including Gilliland's estate at Willsboro, and once again conflict served to suppress settlement of the region (Smith, 1885).

Just after the Revolution, only a few hundred people occupied the Champlain Valley, but by 1810, the population in the valley grew to over 140,000 people including entrepreneurs, land speculators, and new settlers (Lake Champlain Maritime Museum, 2009). The War of 1812 (1812–1815) resulted in one battle in Essex County, when a small British raiding party sailed up the Boquet River at Willsboro and were subsequently driven off by a local militia. The remainder of the conflict was restricted to the northern part of the lake around Plattsburgh and residents of Essex County served in these militias. The war disrupted a lucrative lumber trade with Canada for a brief period, but commerce resumed soon afterwards. When counties were established in New York State in 1683, Essex County was part of Albany County, an enormous county, including northern New York and all of Vermont. After several subdivisions, the New York part of Albany County was split into Albany and Charlotte counties in 1772. Charlotte County, which was later renamed Washington County, was subdivided into Washington and Clinton counties in 1788. Essex County was finally split from Clinton County in 1799.

Forest products became the most important early industry of the county, and use of the county's timber resources began with erecting forts and adjacent settlements in the Champlain Valley, and for the construction of warships and commercial vessels that plied Lake Champlain during the seventeenth, eighteenth, and early nineteenth centuries. Tree species of particular importance in ship building were red pine, white pine, red oak, red spruce, larch, and white cedar (Watson, 1869). Commercial shipyards were located in the villages of Willsboro, Essex, Crown Point, and Ticonderoga, and were viable until around 1875, when the completion of the west shore railroad marked the decline of the industry. As early settlers cleared the land for crops and pasture, excess wood not used for lumber and fuel was burned to produce potash and provided a readily available source of cash or credit (Bernstein, 1971). Hardwoods (beech, birch, maple, oak, cherry, and ash) were the best source, and ashes were leached for lye to produce soap, or boiled down to make potash for use in glass, ceramics, wool production, and fertilizer. Commercial asheries were developed

later on in at least nine of the towns in the county that cleared large areas of forest of hardwoods. Commercial lumbering expanded rapidly after the Revolution, and by 1850, every town in the county had established numerous sawmills producing lumber for local consumption and export (Smith, 1885). Intensive harvesting operations started in the towns along Lake Champlain and worked into the interior of the county. From 1800 until 1824, Canada was the primary market. Timber was cut in the winter, and whole logs banked along rivers for spring drives, or sawn into lumber at local mills and sledded by horse teams to points along the lake. In the spring, sawn lumber was made into cribs or rafts, and piled on top of huge log rafts or towed behind them and sailed north up the lake, then down the Richelieu River to Quebec. Pine and Oak were the most valuable with many ship timbers exported to English shipyards across the Atlantic (Smith, 1885). In 1824, the Champlain Canal opened the markets south to Albany and New York City and the lumber trade increased dramatically. Pine and oak were the most sought after species, followed by spruce, hemlock, and northern hardwoods (Defebaugh, 1907). Canal boats shipped rough and finished lumber, staves, shingles, lath, and other milled products to urban markets, and logs were rafted down the canal to mills along the Hudson River. By 1840, most of the old growth timber used for lumber production had been cut over in the towns bordering Lake Champlain. About the same time, the interior towns, particular Newcomb, North Hudson, Minerva, and Schroon, were just approaching their peak in timber harvesting for lumber production. Some timber was sawn at local mills and used for construction and export, but most of it was transported to downstream mills in spring log drives. Logging was a seasonal occupation with timber being felled, skidded by horse, and piled onto skidways in the late summer and fall. During winter, the logs were hauled by horse teams and sleds to the banking grounds adjacent to rivers, lakes, and ponds, and in spring driven down the rivers running full from the spring snow melt (Welsh, 1995). Red Spruce, white pine, and eastern hemlock were the more important timber species initially being driven down the Schroon and Hudson Rivers and their tributaries. Sawtimber production in the Upper Hudson watershed peaked in 1872 with 189,940,392 board feet (about 2 million logs) reaching the great sorting boom above the mills in Glens Falls (Defebaugh, 1907; Welsh, 1995). New York State led the nation in sawtimber cut in 1850 (Welsh, 1995). Charcoal making was a very important industry during the first half of the nineteenth century. Forges that processed the iron mined in Essex and adjacent counties were established in every town in the county except one (Smith, 1885). “Colliers” manufactured the charcoal that fired the iron forges from nearby hardwood forests of beech, maple, birch, oak, ash, cherry, and hickory. Charcoal burned hotter and cleaner than wood, and was produced by slowly heating the hardwood in the absence of oxygen (pyrolysis), in earthen or brick kilns, driving off moisture and other volatile materials, leaving almost pure carbon (char). Larger forges required a great deal of charcoal, and huge areas were almost completely stripped of timber for production (Welsh, 1995). Charcoal production continued throughout the county from 1800 until the early 1850s when it started being replaced by imported coal from Pennsylvania mines, although some literature suggests that charcoal fired forges operated until the 1870s (Spaulding, 1874). Tanneries existed in the towns of Ticonderoga, Willsboro, Chesterfield, Schroon, Essex, Lewis, Westport, Minerva, and North Hudson and consumed enormous quantities of hemlock bark in their operations. In late spring and early summer, hemlock trees were felled, girdled at 4 foot lengths, and the bark pealed and stacked for shipment (Welsh, 1995). The bark was finely ground and boiled down to extract the tannins, and hides were then soaked in the tanbark liquor. Raw hides for tanning were shipped from the western United States and from South and Central America. Tanneries operated in the county from the 1840s until the 1870s. By the 1870s, the lumber industry was in sharp decline and the pulp and paper industry began its ascension as diameter classes of remaining old growth timber grew smaller, and stands of second growth timber became available. It is notable that

one of the first tree species used in pulp and paper production was yellow poplar, a second growth timber species that was able to naturally revegetate many of these areas cleared for potash and charcoal production, and then grow large enough for pulpwood harvesting by the 1870s (Smith, 1885). Other important pulp species early on were red spruce, balsam fir, and white pine. The Ticonderoga Pulp and Paper Co. and the Glens Falls Pulp Co. both established mills in Ticonderoga in the late 1870s. Both mills were later acquired by the International Paper Co., and in 1968 the mill moved to its present location north of Ticonderoga on Lake Champlain. For years pulpwood was harvested from their own lands and transported to these mills by water, sled, and rail, and later by truck. International Paper currently utilizes a combination of hardwoods and softwoods in the paper making process. The Champlain Fibre Company was established in Willsboro in 1881 and operated until the early 1960s. It initially produced a "dry chemical fibre" (pulp) from yellow poplar harvested from the towns of Willsboro and Lewis (Smith, 1885). The J. J. Rogers Paper Mill was established in Ausable Forks in 1903, and operated until 1971. Much of their pulpwood came from the Ausable River watershed in river drives initially. Finch, Pruyn, and Co. began buying up timberland in the Upper Hudson Basin after 1865, and continued to transport pulpwood in log drives down the Hudson and its tributaries to their mill in Glens Falls until 1950. New York State led the nation in pulpwood production in 1912 (Welsh, 1995). By the 1870s, concern about the condition of forest resources in the Adirondacks by conservation groups led to discussions of preservation. Poor logging practices, land clearing for charcoal and potash manufacturing, subsequent fires, and accelerated soil erosion and sedimentation of streams led to watershed and fisheries degradation, and aesthetically displeasing landscapes in some areas. In 1872 the Commission of State Parks was formed to study the forests condition in the Adirondacks, and in 1885 the Forest Preserve was created. Seven years later, in 1892, the Adirondack State Park was established, and in 1895 "forever wild" legislation prohibited sale, lumbering, or development of any kind on current state-owned lands, and any new lands added to the Forest Preserve within the "Adirondack Park".

Agriculture did not become commercially important in Essex County until lumbering began to slow down, probably sometime in the mid 1800s. There are reports that shipments to Canada of area cattle, beef, pork, butter and cheese were being made as early as 1811 (Cunnion, 1991). Early commercial agricultural products included milk, butter, cheese, beef, wool, wheat, rye, corn, oats, beans, barley, buckwheat, clover seed, flax, maple sugar, beeswax, and honey (US Census of Agriculture, 1850). Land in farms grew steadily from just after the Revolution until 1870 when total land in farms was 456,538 acres, of which 236,000 acres was "improved" farmland, distributed over 2,424 farms. Improved farmland is land in cropland, hayland, or pasture, and the 236,000 acres (20 percent of the county) probably represents the maximum acreage of the county that was ever cleared and developed for agricultural production. By stark contrast, the 2002 Census of Agriculture data shows 55,022 total acres of land in farms, of which 28,731 acres is classified as cropland, distributed over 236 farms. The most dramatic loss of farmland seems to have occurred between 1950 and 1960 when land in farms dropped from 196,741 acres to 126,717 acres, and farm numbers dropped from 1,156 to 529. Historically, the most important agricultural commodities produced in Essex County have been dairy products, wool, wheat, corn, forage crops, birdsfoot trefoil seed, apples, potatoes, and maple sugar. Raising sheep for wool was a very important enterprise in the county from 1850 until around the turn of the century, and may have accounted for a great deal of marginal stony ground being developed for pasture throughout the county, most of which has reverted back to woodland. The table on page 7 shows an interesting snapshot of acres of "improved" farmland reported for various towns in 1870 and 1930. Note that during that period, some towns had abandoned nearly two thirds of their improved farmland. Employing machinery for tillage and transportation instead of horses after the turn of the century, may also have accounted for the abandonment of a great deal of marginal pasture and hayland.

"Improved" Farmland Reported of Selected Towns
US Census of Agriculture

Town	Approximate Total Acres	1870	1930
Chesterfield	66856	21029	6453
Crown Point	52195	20919	8277

Willsboro	46758	20044	7313
Wilmington	41765	---	2412

Sheep production reached its peak in 1870 with nearly 63,000 head reported. This same year, New York State ranked second in the nation behind Ohio in sheep numbers, and Essex County ranked ninth in the state (US Census of Agriculture, 1870). As interest in wool production waned, mainly due to failing markets, dairy production steadily increased, reaching a peak in 1900 with 11,266 dairy cows reported. After 1900, dairy production steadily decreased with about 1,983 dairy cows reported in 2002. For years after the arrival of the early settlers, wheat was the predominant crop in Essex County, as well as the entire Champlain Valley. The average yield was about 25 bushels per acre. Wheat production peaked in the county with about 70,000 bushels harvested in 1860, with Willsboro, Essex, Crown Point, and North Elba being the highest producing towns (Cunnion, 1991). Production rapidly dropped and by 1900 was less than 1,600 bushels for the entire county (US Census of Agriculture, 1900). In 2002, about 6,740 bushels of wheat were produced. Corn and hay crops became important feed and forage for dairy cattle. Corn for grain at first was grown, and then later on corn silage production took over. During the 1940s growing birdsfoot trefoil for seed became a hot item in the county. It was called "brown gold" and "the Cinderella crop" because of the excellent profits it afforded. The production peaked in 1957, but by the 1960s the boom collapsed due to domestic and foreign competition and blights (Cunnion, 1991). Apples were also an important crop produced in the county with 128,251 trees reported by 1900. In 2002 there were 8 farms with orchards located primarily in Chesterfield and Crown Point. Irish potatoes were an important vegetable crop early on with 411,777 bushels reported in 1860. Only 3 farms reported production in 2002, mostly south of Lake Placid. Maple sugar production was important to early settlers for generating cash, and peaked in 1889 with 161,169

pounds reported (Cunnion, 1991). Maple syrup is still produced in the county with 28 sugar bushes reporting 4,845 gallons of syrup produced in 2002.

Mining was a very important part of the county's development. The earliest accounts tell of Phillip Skene mining exposed beds of iron ore just north of Port Henry village in 1766 (Essex County Historical Society, 2009). One of the oldest iron works in Essex County was established at New Russia in 1802 and operated until about 1866. The ore used was obtained from the New Russia mine and from the Fisher Hill Ore Bed. Major James Dalliba and John Dickenson erected the first furnace at Port Henry in 1822, obtaining the ore from a vein nearby. The Town of Moriah was a major producer of iron ore for many years. Mines were privately owned until 1850. Then the Witherbee, Sherman Company acquired the mines in 1851 and operated them until 1938, eventually becoming the largest producer of iron ore in the nation prior to World War II. The Republic Steel Corporation then acquired the mines in 1938, and operated them until 1971. The MacIntyre Development began near Tahawus, in the Town of Newcomb, when iron ore was discovered in 1826. MacIntyre and his partners started producing iron in 1838 and continued until 1855 when financial problems resulting from transportation difficulties, and costs of separating large amounts of titanium in the ore shut them down. An attempt to revive the operation in 1894 by the MacIntyre Iron Company was unsuccessful after only 20 years, and in 1941 the National Lead Company acquired the deposits and operated the mine until 1982. Ilmenite, the titanium bearing mineral that had been such a problem to the previous owners, had become the focus of the operation, and the site became one of the world's largest titanium mines, with iron just a co-product. Titanium oxide became important as a pigment in many products, and as a main ingredient in the production of chemical smokes used in warfare. In the town of Crown Point, iron ore was discovered in 1821 and developed by Charles Hammond, and again in 1826 near Ironville and developed by Allen Penfield. The work of these two men eventually led to the establishment of the Crown Point Iron Company. The operation produced iron ore until 1893, and was noted for being the site of the first industrial application of electricity being employed in the ore separating process (Allen, 1967). Wollastonite was first discovered in 1810 in the town of Willsboro, but mining and processing of the mineral did not gain momentum until Koert Burnham began to develop deposits in Willsboro shortly before World War II. One of the first applications was the manufacture of electric insulators for use on the Manhattan Project (Cunnion, 1985). Northern Minerals was established just after the war, and in 1979, NYCO Minerals assumed operation of the mines and processing center in Willsboro. NYCO Minerals still produces wollastonite today, which is used in paints and coatings, construction and welding materials, ceramics, and automotive parts. Graphite was discovered on Lead Hill in the town of Ticonderoga in 1815, which was used in polishes, and eventually the manufacture of the familiar Ticonderoga pencil by the American Graphite Company. Quarrying has also been a notable venture in the county's history in the towns of Willsboro, Essex, and Jay. In 1869, S. W. Clark and Company's limestone quarry on Ligonier Point in the town of Willsboro supplied foundation stones for New York's state capitol building, and stone for piers of the Brooklyn Bridge (Essex County Historical Society, 2009).

Tourism has also been important to the development of Essex County. Keene Valley, Lake Placid, and Saranac Lake have been hosting visitors since the late 1800s to experience the beauty of the Adirondack's mountains and lakes. Grand hotels were established in several locations around the county in the late nineteenth century including the Leland House on Schroon Lake, the Deer's Head Inn and Windsor Hotel in Elizabethtown, and the Lake Placid Club and Grand View House in Lake Placid. Newcomb was the home of two of the “Adirondack Great Camps”: Santanoni and the Huntington Estate (now the Adirondack Ecological Center). Camp Dudley, the oldest operating YMCA camp in the nation, was established on Lake Champlain south of Westport in 1891 (Essex County Historical Society, 2009). Wilderness resorts such

as the Elk Lake Preserve (now Elk Lake Lodge) in the town of North Hudson, the Adirondack Mountain Reserve (now the Ausable Club) in the town of Keene, and the Tahawus Club in the town of Newcomb were established around the beginning of the twentieth century. In 1870, Ausable Chasm on the Ausable River north of Keesville, began operation as a tourist attraction (Essex County Historical Society, 2009). Several art and music schools were established in the early to mid 1900s which still operate today, including the Seagle Colony in Schroon Lake, the Old Mill Art School in Elizabethtown, and the Meadowmount School in Lewis. In the 1940s and 1950s, during the heyday of the "theme park", several parks were established in the county including "Santa's Workshop" in Wilmington which is still in operation, Arto Monaco's "The Land of Make Believe" in Upper Jay, and "Frontier Town" in North Hudson.

Transportation and Industry

Travel in Essex County is served along its eastern edge by Interstate 87, US Route 9, Amtrak rail line, and Lake Champlain. Interstate 87 (also known as the Adirondack Northway) runs north from Albany, NY through Keeseville and Plattsburgh, NY to the US-Canadian border, and connects via the Canadian highway system to the city of Montreal, Quebec. The railroad, which runs adjacent to Lake Champlain in Essex County, consists of both the Amtrak New York City to Montreal, Quebec passenger service, with stations at Ticonderoga, Port Henry, Westport, and Port Kent; and the freight service owned by Canadian-Pacific Railroad. Maritime service connects Lake Champlain to the Hudson River and Albany, NY via the Champlain Canal on the south, and to the St. Lawrence River and Montreal, Quebec on the north via the Richelieu River and Chambly Canal. Ferry service across Lake Champlain from Essex County to Vermont connects Burlington, Vermont to Port Kent, New York and Charlotte, Vermont to Essex, New York. Local routes running along Lake Champlain consist of NYS Routes 22 and 9N. US Route 9 runs roughly parallel to the Adirondack Northway south to north from Schroon Lake to Keeseville. Travel routes to points in the western part of Essex County are split by the Adirondack High Peaks Region. In the southern part of the county, NYS Route 74, the Blue Ridge Road, and NYS Route 28N connect Ticonderoga to Schroon Lake and Newcomb. In the central part of the county, NYS Routes 9N, 73, and 86, connect Westport to Elizabethtown, Keene, Lake Placid, and Saranac Lake. In the northern part of the county, NYS Routes 86 and 9N connect Saranac Lake to Lake Placid, Wilmington, Jay, and Ausable Forks.

The economic base of Essex County is still to a large degree dependant on its natural resources. Tourism and hospitality account for a major portion of the employment within the county. Natural attractions such as the Adirondack High Peaks Region, over a half a million acres of New York State Forest Preserve lands, nearly 77,000 acres of lakes and ponds distributed over 390 water bodies, and approximately 200 miles of scenic rivers help to draw nearly three quarters of a million visitors annually to the county. Nearly 20 percent of the private workforce is employed in accommodation and food services, arts, entertainment, recreation, rental and leasing, retail sales, and all supporting at least in part the tourism economy (SUNY Potsdam, 2004). Historical attractions such as Fort Ticonderoga and Fort Crown Point along Lake Champlain, and the John Brown Farm near Lake Placid also support the local economy. The Olympic Regional Development Authority operates the Whiteface Mountain Ski Center, the Olympic Arena, Bob Sled Run and Ski Jumps, and Olympic Training Facility in Lake Placid, which all contribute to the local economy. The New York State Department of Environmental Conservation administers ten public campgrounds and numerous boating and fishing access sites throughout the county.

The forest products industry is also an important part of the county's economic base. Timber harvesting for lumber, and wood pulp for paper products, occur on over half a million acres of private forest lands, of which about 17 percent is large industrial forest land holdings. Forest products account for about seven percent of the private

workforce including loggers, foresters, lumber mill operators, specialty products manufacturers and furniture makers, retail and wholesale forest products outlet operators, and one paper mill which employs about 700 workers (Essex County IDA, 2009). Important paper producing tree species include sugar and red maple, yellow birch, beech, red oak, and white pine. Saw timber for lumber that is harvested in the county mainly consists of white pine, red pine, red oak, black cherry, white ash, and sugar maple. Due to uncertain energy prices, demand for firewood is growing rapidly. Hardwoods make the best firewood and include cherry, oak, beech, maple, birch, and hop hornbeam. Examples of specialty products produced in Essex County forests are fence posts from eastern white cedar and ginseng.

Agriculture is an important part of Essex County's economy and consists primarily of dairying. In 2002 there were 236 farms on 55,022 acres of land, representing about five percent of the land area of the county. Average farm size was about 233 acres (US Census of Agriculture, 2002). Most of the active agricultural land is located in the Champlain Valley along the eastern edge of the county. Dairy farms with some small vegetable operations are distributed throughout the valley, and two major apple growing areas lie in the towns of Chesterfield and Crown Point. Some dairying and vegetable crops are grown in the Ausable River valleys (west and east branches), and potatoes are grown on the gently sloping till plains south of Lake Placid. Leading agricultural products include dairy products, hay and other crops, vegetables, orchards, nursery and greenhouse, and other products (NYASS, 2002). Although farm employment made up less than one percent of the workforce, it accounted for 8.5 million dollars in sales in 2002.

Mining in the county was more widespread in the past. Current operations include wollastonite mining in the towns of Willsboro and Lewis, quarrying for dimension stone in the town of Jay, sand and gravel extraction from glacial outwash deposits scattered throughout the county, and some reprocessing of mine tailings for aggregate in Newcomb.

Retail sales, construction and development, financial and legal services, professional and technical services, small scale manufacturing, and other kinds of industries and institutions all contribute to the local economy. Other important employment in the public sector includes town, county, and state government, state and federal corrections institutions, health care facilities, and educational institutions.

Physiography and Geology of Essex County

Dr. David A. Franzi, Professor of Geomorphology at the State University of New York in Plattsburgh, prepared this section.

Physiography

Most of Essex County lies in the Central Highlands section of the Adirondack Mountains (Isachsen, et al., 1991). The Adirondack Mountains are an upland region of moderate to high relief that is underlain by high-grade middle Proterozoic metamorphic rocks. Cressey (1977) further differentiated the upland into the Adirondack Mountain Peaks, where mountain summits exceed 900 meters (~3000 ft) and the surrounding Adirondack Low Mountains. The Adirondack Mountain Peaks section in Essex County includes Mount Marcy (1,629 m, 5,344 ft), the highest peak in New York, and all but four of the 46 highest peaks in the Adirondack Mountains. Much of this region is underlain by the Marcy anorthosite massif (McLelland and Wong, 2008). Local relief in this section exceeds 600 meters (~1950 ft), nearly double that typically found in the Adirondack Low Mountain section.

The Adirondack Upland is a structural dome, a roughly circular uplifted region in which the original sedimentary rock cover has been removed by erosion. Exhumation (unroofing) of the Adirondack dome accompanied uplift and continues to the present day. Widespread unroofing probably began in the middle Jurassic as evidenced

by apatite fission-track (AFT) and uranium-thorium/helium ((U-Th)/He) ages from metamorphic rocks in the region, and continued through the late Cretaceous (Roden-Tice and Tice, 2005). AFT age discontinuities between the Adirondack High Peaks region and the southeastern portion of the upland further suggest that differential unroofing may be related to fault reactivation (Roden-Tice and Tice, 2005).

The easternmost portion of the county lies in the St. Lawrence-Champlain Lowlands (Isachsen, et al., 1991; Cadwell, et al., 2003) or the Champlain Lake Plain Section of Cressey (1977). The former shoreline of the Coveville Stage of proglacial lake Vermont (Franzi, et al. 2007) provides a functional boundary between upland and lowland regions. The Coveville shoreline rises from about 157 meters at the Street Road delta in Ticonderoga to 202 meters at the Clintonville delta in the AuSable valley (Kemp and Alling, 1925; Chapman, 1937; Rayburn, 2004; DeSimone, et al., 2008). The lowlands are underlain by middle Proterozoic metamorphic rocks, lower Paleozoic sedimentary rocks and unconsolidated glacial and post-glacial sediment. The upland-lowland boundary is commonly marked by a pronounced change in slope associated with abrupt changes in bedrock lithology along fault-line scarps. In some areas, however, the boundary terrain is characterized by low hills underlain by metamorphic rocks that are surrounded by gently rolling plains underlain by late-glacial lacustrine deposits. Steep upland terrain extends eastward to the shoreline of Lake Champlain near Trembleau Mountain, Willsboro Bay, Split Rock Mountain, Bulwagga Bay and Ticonderoga. Local relief in the lowlands generally ranges from a few meters to a few tens of meters. The lowest elevation in the county is 29 meters (95 ft) at the Lake Champlain shoreline. The lowest elevation below Lake Champlain is approximately 93 meters (305 ft) below sea level near Split Rock Point.

The sedimentary strata in the lowlands flanking the upland dip gently away from the center of the Adirondack dome. Modern drainage patterns are strongly influenced by regional geology and structure. Drainage is generally radial off the dome and tangential in the peripheral lowlands (Ruedemann, 1931; Morisawa, 1985). Parts of three regional drainage systems, Lake Champlain, Hudson River and St. Lawrence River systems lie within Essex County (fig. 2). More than 60 percent of the county drains to the north and east to Lake Champlain and ultimately to the St. Lawrence estuary via the Richelieu River. The principal watersheds in the Lake Champlain basin are the AuSable and Boquet, which originate near the Champlain-Hudson divide in the High Peaks and flow northeastward to Lake Champlain at Keeseville and Willsboro, respectively. The northwestern portion of the county drains to the Saranac watershed and several smaller basins drain directly to Lake Champlain south of Westport. The Hudson River originates in the High Peaks region north of Tahawus and flows generally southward to its confluence with Indian River. From this point, the river flows southeastward forming the southern boundary between Essex and Hamilton counties for a distance of about 21 kilometers. The river leaves the county at North River near the intersection of Essex, Hamilton and Warren counties. Principal tributaries to the main channel of the Hudson River include the Opalescent, Newcomb, Goodnow, Cedar and Boreas rivers. The eastern portion of the Hudson River watershed in Essex County is drained by the Schroon River, which joins the Hudson in Warrensburg. The upper reaches of the Raquette River drain two small areas of the county west of the Santanoni Mountains and northwest of the Fishing Brook Range. These areas represent the only parts of the St. Lawrence drainage system in Essex County and account for less than 5 percent of the county's surface water drainage.

Bedrock Geology

The metamorphic rocks in the Adirondack uplands of Essex County were formed during the Grenville Orogenic Cycle (McLelland et al., 1996), which consisted of three major Mesoproterozoic mountain-building episodes (orogenies) between about 1350–1000 million years BP (fig. 3). Most consist of severely deformed, granulite

Figure 2.—Physiographic subdivisions and principal drainage basins in Essex County.

facies metaigneous rocks, such as tonalitic, granitic, charnockitic and anorthositic gneisses. The Marcy anorthosite massif underlies most of the region and accounts for the highest and most rugged terrain in Essex County. The Marcy massif consists of anorthosite, mafic anorthosite, leucogabbro and gabbro that were emplaced between about 1160–1150 million years BP. The anorthositic rocks were most likely derived from mantle melts while related and coeval mangerites, charnockites and granites are probably due to crustal melting associated with anorthosite emplacement (McLelland, 2008). Early mountain building culminated during the Ottawan Orogeny (around 1100-1000 million years BP) when the rocks of the present Adirondack region were involved in a Himalayan-style continental collision between Laurentia (early North America) and Amazonia (early South America). The suturing of these continents and other Mesoproterozoic landmasses resulted in the assemblage of the supercontinent Rodinia. Regional granulite-facies metamorphism associated with this orogenic event probably occurred at crustal depths exceeding 25 kilometers (Bohlen et al., 1985; McLellend et al., 2001) and over-printed much of the evidence for earlier events (McLelland et al., 1996). Prolonged post-orogenic exhumation exposed the metamorphic core complex by the end of the Neoproterozoic.

Rifting of Rodinia began at the end of the Neoproterozoic, resulting in the formation of the Iapetus Ocean. Lower Paleozoic sedimentary rocks record transgression of the Iapetus shoreline onto the rifted margin in what is now northeastern New York (fig. 4). The middle Cambrian Potsdam Formation forms base of the sedimentary sequence in Essex County (Landing, 2007). The nonconformity between the Mesoproterozoic basement rocks and the lower arkosic sandstone and conglomerate unit (Ausable Member) of the Potsdam Formation spans more than 500 million years and is well exposed in roadside outcrops along Route 22 in nearby Warren County (Selleck, 2008). In northern Clinton County, the Potsdam Formation conformably underlain by the Altona Formation, a newly defined late-early to middle Cambrian sandstone,

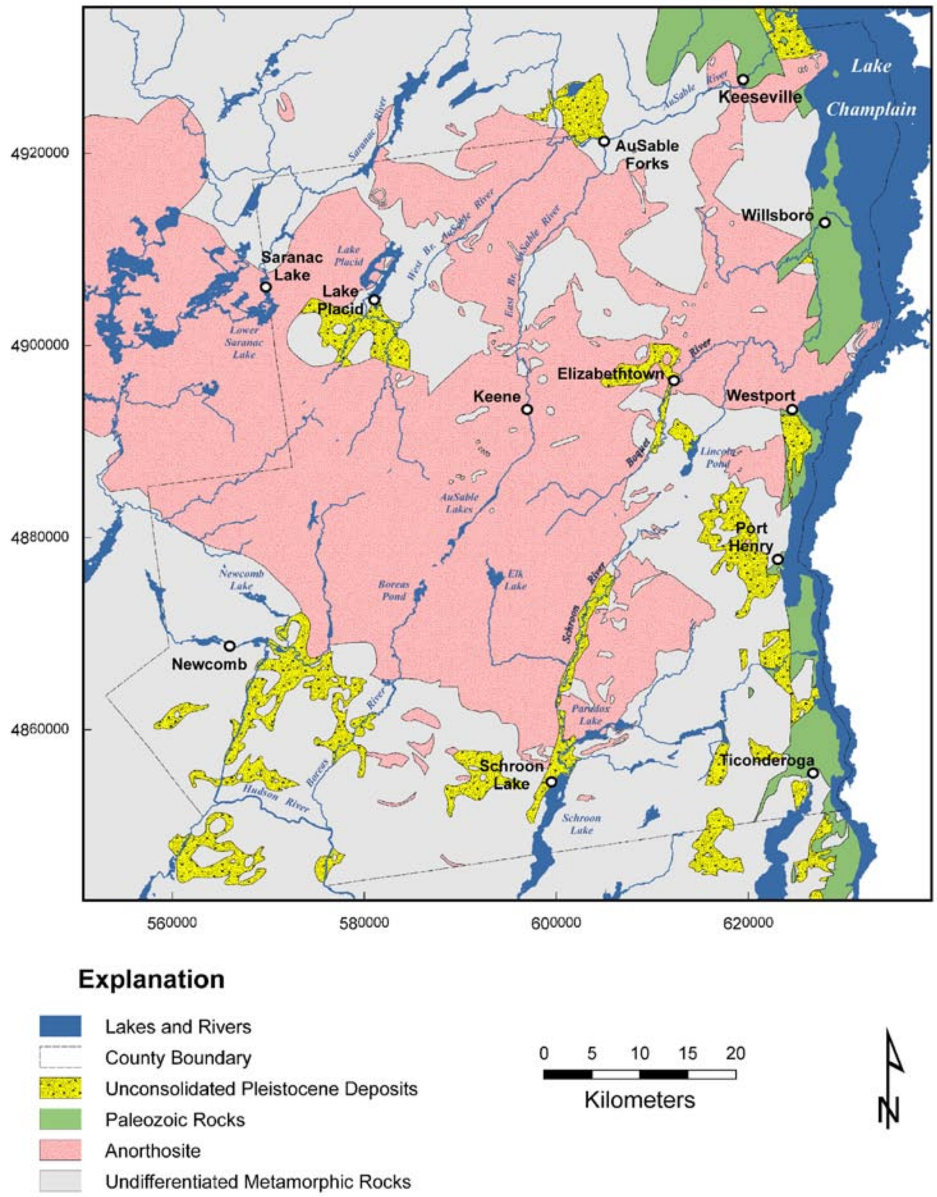

Figure 3.—Generalized bedrock geology of Essex County (from Isachsen and Fisher, 1995).

shale and dolostone unit (Landing et al., 2009, in press), thus, Cambrian marine onlap along the Laurentian margin in northeastern New York was asynchronous. The Potsdam Formation is overlain, in ascending order, by the upper Cambrian to middle Ordovician Beekmantown Group (predominantly carbonates), middle-upper Ordovician Chazy Group (carbonates) and the upper Ordovician Black River (carbonates) and Trenton (carbonates and shale) groups (Isachsen and Fisher, 1995; Landing et al., 2007). Lower Paleozoic sedimentary rocks in Essex County are restricted to a narrow (generally less than 5 km wide), discontinuous, typically fault-bounded outcrop belt along the shoreline of Lake Champlain.

Economic mineral deposits occur throughout the Adirondack Upland in Essex County. Iron-bearing ore deposits in the region have been mined since the early

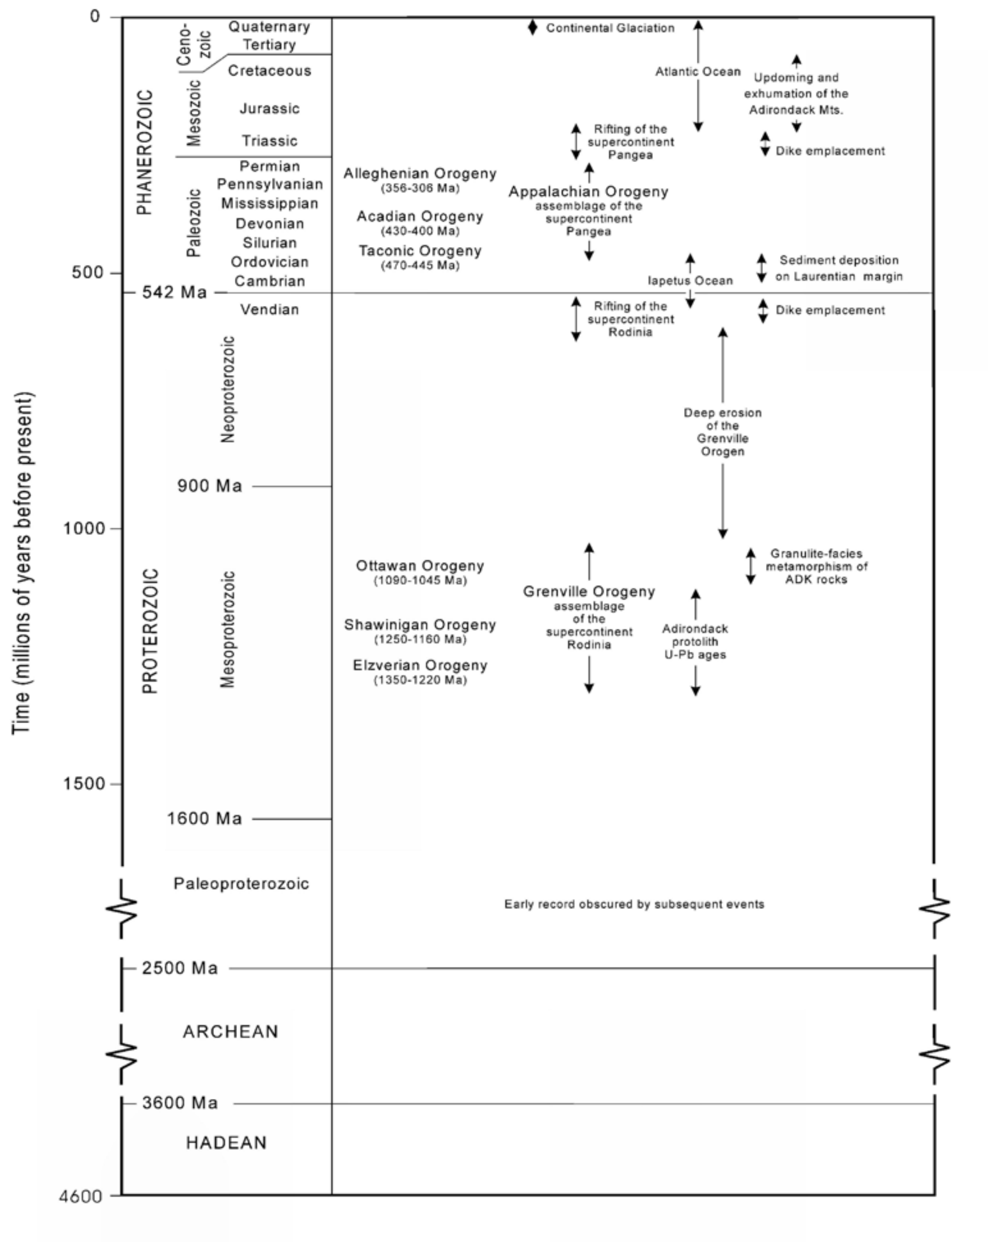

Figure 4.—Timeline for geological events in northeastern New York.

nineteenth century (Dawson et al., 1988; Lupulescu and Pyle, 2008). The most productive iron-mining district was the Mineville–Witherbee complex in Moriah (Dawson et al. 1988) where magnetite was the primary ore mineral. Mines in the Black Brook, Cook Mountain, Arnold Hill and Palmer Hill area, supported the iron industry in the Ausable Valley (Postel, 1952; Whitney and Olmsted, 1993). The mining industry in Essex County peaked during and immediately after the Civil War but began to decline by the end of the century. Only the mines in the Mineville–Witherbee–Fisher Hill area remained active into the early twentieth century (Dawson et al. 1988) and these were ultimately closed in 1971 (Lupulescu and Pyle, 2008). Mining operations at Tawahus began in the early nineteenth century for magnetite (Darling and Kelly, 2008) but these early operations were at best marginally successful because of the high ilmentite content of the ore (Isachsen et al., 1991). National Lead Company reopened

the mine during World War II for the mineral ilmentite from which titanium oxide was extracted. Mining at Tahawus ended in 1982 and the site was reclaimed in 2005-2006 (Darling and Kelly, 2008). Wollastonite skarn is associated with metanorthosite in an approximately 22 kilometer-long zone between Willsboro and Lewis (Whitney and Olmsted, 1993; Peck and Bailey, 2008).

Wollastonite has many commercial applications including its use as a ceramic base, welding flux, alloying agent, plastics extender, paint pigment and a substitute for asbestos. Although wollastonite deposits were identified in the mid-nineteenth century, commercial mining did not commence until 1953 near Willsboro. Mining operations shifted from the Willsboro mine to an open-pit near Lewis in the early 1980s. Presently, NYCO produces wollastonite from the Lewis mine and plans future production at the Oak Hill mine.

Glacial Geology

Cadwell and Pair (1991) provide the most comprehensive compilation of surficial materials in the region to date. Surficial deposits are essentially nonexistent on most Adirondack high peaks but exceed 30 meters in thickness at some locations in upland valleys and the Champlain Lowland. Relatively thin (generally < 5 m thick) deposits of till and colluvium mantle upland slopes throughout the Adirondack Upland. Till deposits commonly overlie polished bedrock surfaces that may contain ice-flow direction indicators such as striations, friction cracks and crescentric gouges. The composition and texture of glacial tills in the region are variable and reflect local source terranes (Franzi et al., 2007). Till in upland valleys and the Champlain Lowland is commonly buried beneath a variable thickness of younger glacial, glacial foreland (i.e. those deposits associated with ice-marginal environments), and nonglacial deposits.

The oldest glacial deposits in Essex County were first described by Muller (1965a, 1965b, 1969) and Craft (1969) from an exposure of multiple tills interbedded with lacustrine sediment at the open-pit mine at Tahawus. Wood fragments from lake mud between two tills yielded uncorrected 14C ages of > 41,000 years BP and > 55,000 years BP (W-1451 and Y-1715, respectively). Note that all subsequent radiocarbon ages presented in this discussion are calibrated or “calendar” ages unless specifically identified as uncorrected 14C ages. The presence of pollen from hardwood species that are no longer found in the region in a pollen profile between the lowermost tills led Muller et al. (1993) to conclude that the mud was deposited during a nonglacial interval that was warmer or longer than the present. Muller et al. (1993) suggested that the warm interval represented by the pollen data best correlate with isotope stage 5e, which roughly coincides with the Pre-Wisconsinan Sangamon Interglacial. They further suggested that the lack of cold-climate pollen at the top of the pollen profile was due to erosion by subsequent ice advances.

Most glacial deposits in the region are associated with the retreat of the Hudson-Champlain lobe during the waning of stages of the Late Wisconsinan glaciation. Deglacial drawdown of ice in Adirondack valleys and the Champlain Lowland hastened thinning of ice in upland regions and caused lobation of the ice margin. Deglaciation of the east-central Adirondack Upland and west-central Champlain Lowland region probably began after 14,000 years BP (Muller and Calkin 1993; Ridge 2003; Franzi et al., 2007). The regional and stratigraphic distribution of these deposits generally conforms to a model of systematic northward recession of active continental ice lobes in Adirondack valleys and the Champlain Lowland (e.g. Diemer and Franzi, 1988; Franzi, 1992; Rayburn et al. 2005, 2007; Franzi et al., 2007).

Craft (1976) described the relationship between the Blue Ridge Moraine and glacial Lake Warrensburg (Miller, 1925) in the upper Schroon River Valley. The moraine was build by ice that originated in the upper Hudson River drainage basin and flowed eastward through The Branch Valley to a position near Blue Ridge (Craft, 1976). Meltwater outflow from the ice margin deposited an outwash valley train that was

graded to a delta built into glacial Lake Warrensburg in the upper Schroon Valley. A minimum age of about 13.1 thousand years BP (uncorrected 14C) for glacial Lake Warrensburg, and by association the Blue Ridge Moraine, is provided by a bog-bottom date from outwash associated with the Luzerne Readvance (Connally and Sirkin, 1971). Younger outwash filled The Branch Valley behind the moraine following drainage of Lake Warrensburg and further up-valley retreat of the ice margin (Craft, 1976).

North of the Hudson River–Lake Champlain drainage divide, the receding ice margin commonly blocked local north- or east-draining valleys and created proglacial lakes that expanded with ice-margin recession. The general chronology of late glacial events in the region is best understood from the analysis of glacial foreland deposits and landforms and their relationships to proglacial lakes. Northward expansion of proglacial lakes in the Ausable and Boquet valleys was punctuated by sudden lake-draining breakouts as lower outlets were uncovered as the ice margin receded (Diemer and Franzi, 1988; Franzi, 1992). Figure 5 provides an example of the drainage and lake-level changes that occurred in the Ausable and Boquet valleys near Elizabethtown about 13.2 thousand years BP (Franzi, 1992; Rayburn et al., 2007). Examples of outflow channels and channel systems that are associated with breakout floods and sustained proglacial lake outflow in Essex County include the Channel Belt between Lewis and Ausable Forks (Kemp and Alling, 1925), the channel system at Wilmington Notch, and the Black Brook channel (Diemer and Franzi, 1988). Regional correlations of upland proglacial lake sequences (Diemer and Franzi, 1988; Franzi, 1992) are consistent with generally synchronous ice recession in adjacent valleys. Local upland proglacial lakes in the Lake Champlain drainage basin were succeeded by Lake Vermont and later by the Champlain Sea as ice receded northward in the Champlain Valley.

Glacial Lake Vermont in the Champlain Lowland was the largest proglacial lake in the region. Chapman (1937) recognized two stages of Lake Vermont, which he named the Coveville (upper) and Fort Ann (lower) (fig. 6). Lake Coveville was probably confluent with coeval proglacial lakes in the Hudson Lowland but their relationship remains elusive. The outlet for the Fort Ann Stage was located on the Champlain-Hudson drainage divide near Battle Hill north of Fort Ann in Warren County and

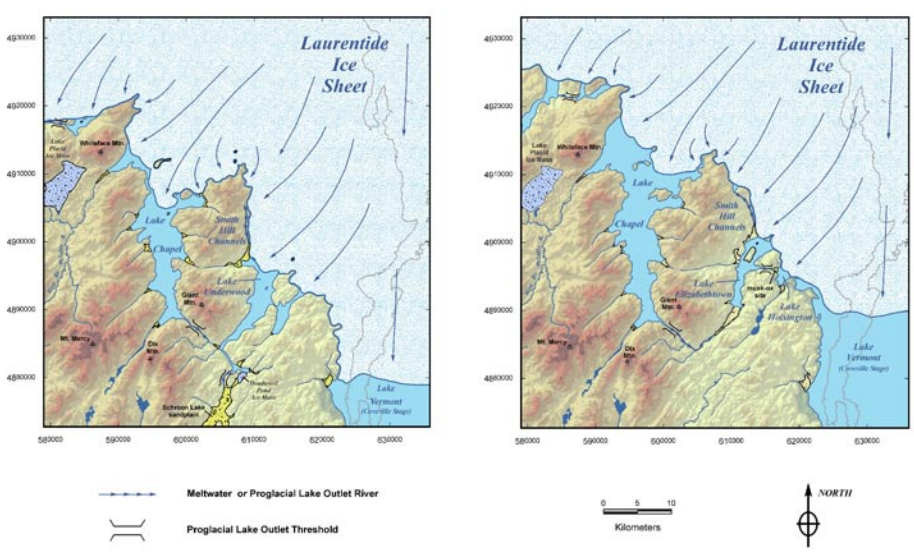

Figure 5.—The shaded relief Digital Elevation Model (DEM) maps of the Ausable and Boquet valleys near Elizabethtown show the paleogeography and ice margin immediately prior to and after deposition of the musk-ox bone (from Rayburn et al., 2007).

outflow was directed southward into the Hudson drainage basin. Franzi et al. (2002; 2007) and Rayburn et al. (2005) traced Coveville shoreline features northward to Cobblestone Hill and Altona Flat Rock (Clinton County) and suggested that the breakout of proglacial Lake Iroquois in the Ontario and St. Lawrence lowlands simultaneously scoured the Flat Rocks in Clinton County, deposited the Cobblestone Hill moraine and caused the level of Lake Vermont to drop from the Coveville to Fort Ann level. Rayburn et al. (2007) reported two radiocarbon dates from organic materials in lacustrine deposits from Essex County that bracket these events. A portion of musk-ox vertebra found in prodeltaic rhythmites in a gravel pit near Elizabethtown yielded calibrated dates in the range of 13.4 to 13.0 thousand years BP. The bone date corresponds to an ice marginal position near Elizabethtown and the Coveville Stage of

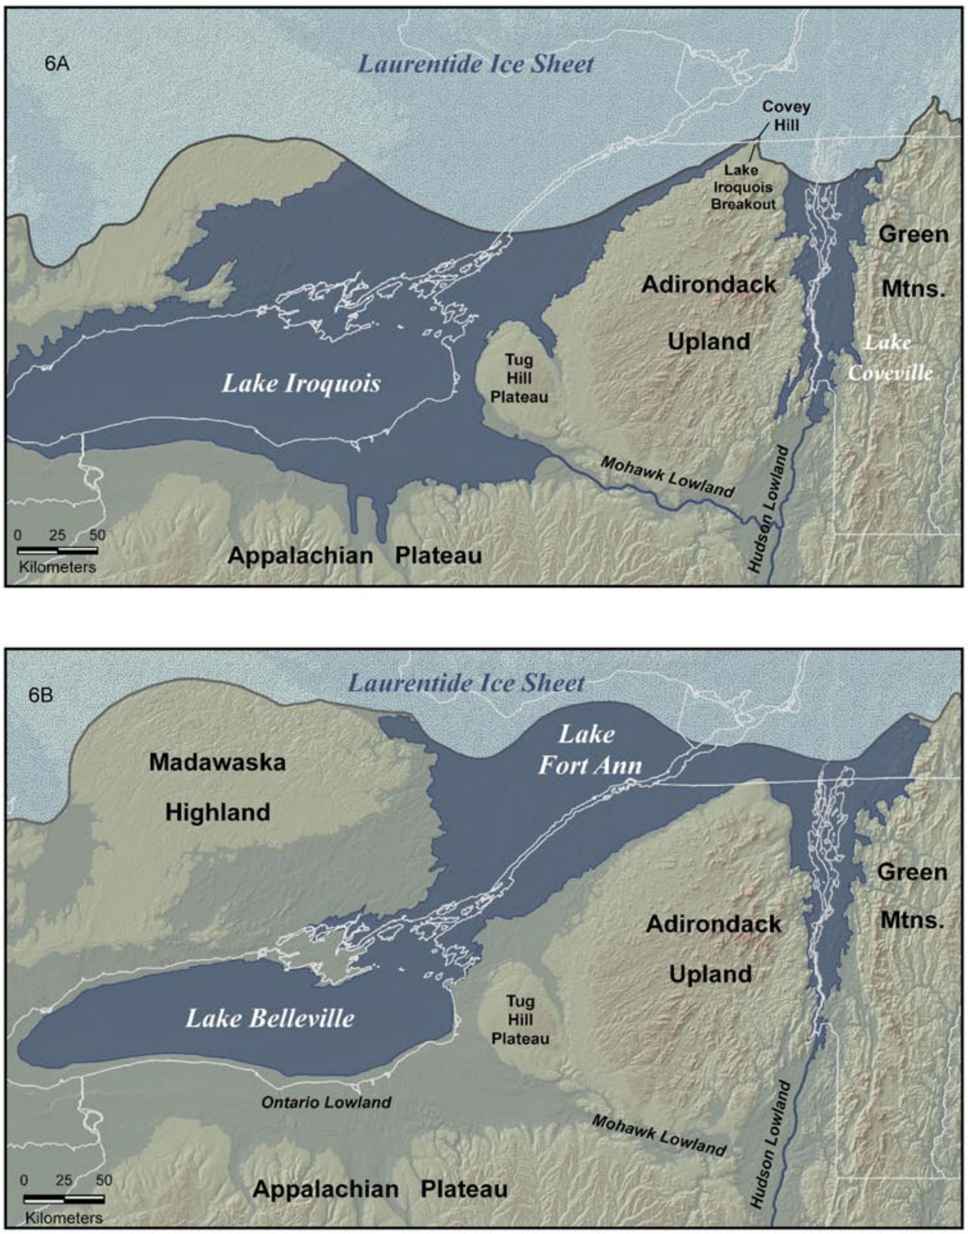

Figure 6.—Successive stages of Glacial Lake Vermont (6A and 6B) with respect to the receding Laurentide Ice Sheet.

Lake Vermont. A second date of 13.0 to 12.7 thousand years BP from Long Pond near Willsboro dates the drop from the Coveville level to the present level of Long Pond, and thus dates the ice margin at Cobblestone Hill in Clinton County (Rayburn et al., 2007). Late Wisconsin ice-retreat rates estimated from these dates and other geochronologic evidence from the Champlain Lowland generally fall in the range of 0.2 to 0.5 km/yr (Franzi et al., 2007).

Ice recession from the north flank of Covey Hill in southwestern Quebec caused proglacial lakes in the St. Lawrence Lowland to drain to the Fort Ann level. The merged proglacial water bodies are known by different names in the St. Lawrence Lowland (see discussions in Pair and Rodrigues, 1993 and Franzi et al., 2007), however, the Fort Ann outlet continued to control water level and direct outflow southward through the Champlain and Hudson Lowlands during this time.

Ice margin recession from the Appalachian piedmont in southern Quebec, drained proglacial Lake Vermont (Fort Ann Phase), opened connection to the western Goldthwait Sea in the Gulf of St. Lawrence, and allowed marine water to inundate the isostatically depressed St. Lawrence and Champlain Lowlands. The marine incursion, known as the Champlain Sea, persisted until isostatic uplift isolated the Champlain Lowland from the St. Lawrence estuary and established early Lake Champlain. Preliminary analyses of microfauna extracted from radiocarbon-dated sediment cores from Bulwagga Bay suggest that saline or brackish water conditions may have lingered in this portion of the Champlain Basin until approximately 8.9 thousand years BP (J. Rayburn and T. Cronin, personal communication, 2009).

Lacustrine and marine deposits associated with proglacial Lake Vermont and the Champlain Sea were deposited in off-lapping sequences as water levels in the Champlain Lowland fell during deglaciation. Deltaic sandplains mark the locations where the rivers entered the regional water bodies in the lowland. Large Coveville Stage deltas occur at Elizabethtown (Boquet River), The Plains (North Branch Boquet River) and Clintonville (Ausable River). Fort Ann Stage deltas for these same rivers are found down-valley at I-87 between Elizabethtown and Wadhams, east of Reber and north of Keeseville (Clinton County), respectively. A large marine delta deposit occurs in the lower Boquet River at Willsboro. Thick deposits of glacial lacustrine and glacial marine sand and mud occur in a narrow band parallel to the Lake Champlain shoreline. These deposits are prone to small slumps (generally < 1 hectare) (Newland, 1938; Buddington and Whitcomb, 1941; Franzi et al., 2007).

Several published accounts document evidence for local alpine glaciation in the High Peaks following recession Late Wisconsinan continental glaciers (e.g. Johnson, 1917; Alling, 1918, 1920; Kemp and Alling, 1925; Craft, 1976). More recently, Waitt and Davis (1988), Ackerly (1989) and Davis (1999) reviewed published evidence for local glaciation in the northeastern United States and concluded that many deposits and landforms ascribed to Late Wisconsinan alpine glaciation may be relict features or can be attributed to wasting continental ice lobes and post-glacial processes. No evidence has yet been found for the possible perturbation of the proglacial lake successions in the Ausable and Boquet basins due to the expansion of Late Wisconsinan alpine glaciers. Furthermore, the occurrence of high-elevation lacustrine deposits (> 700 meters above sea level), dammed by continental ice lobes in the upper Spruce Mill Creek and Roaring Brook (Barclay, 1993) watersheds, indicate that Late Wisconsinan alpine glaciation was probably less extensive than proposed by Craft (1976). Radial outflow associated with an Adirondack ice dome at the margin of the Laurentide Ice Sheet (Hughes and others, 1985) may explain some of the local flow patterns described by Craft (1976) but the inferred dome must predate the deglaciation of the Ausable and Boquet valleys.

Drainage

The drainage system of Essex County is separated into two major systems: The Lake Champlain-St. Lawrence River system and the Hudson River system (fig. 7). The drainage from the northern half and southeastern edge of the county flows northward and eastward into the Lake Champlain-St. Lawrence River system, and the drainage from most of the southern half of the county flows southward into the Hudson River system.

About 55 percent of the county lies within the west-central and southwest Lake Champlain watershed, which drains northward via the Richelieu River to the St. Lawrence River. The principal drainage basins in this part of the county are the Ausable, Boquet, and Upper Saranac. Minor sub-basins that drain directly into central and south Lake Champlain are Willsboro Bay-Lake Champlain, Westport-Lake Champlain, Witherbee, McKenzie Brook, Bullwagga Bay-Lake Champlain, Putnam Creek, Fivemile Creek-Lake Champlain, and Trout Brook. A very small portion of the county lies in the Lake George basin. The Saranac River, which originates in the central Adirondack Upland near Saranac Lake, drains a small area (about 5 percent) of the county in the very northwest corner. The Ausable and Boquet Rivers originate in the Adirondack High Peaks Region, flow northeast toward Lake Champlain, and drain most of the northern half of the county. The Ausable River enters the lake just north of Keesville and the Boquet River enters the lake at Willsboro. The various minor sub-basins mentioned above originate in the eastern foothills of the county which lie between the High Peaks and the Champlain Valley, flow generally eastward toward Lake Champlain, and drain most of the eastern foothills and most of the area of the Champlain Valley that lies within the county.

The Upper Hudson watershed drains about 42 percent of the county south into the main Hudson River. The principal sub-basins of the Upper Hudson within the county are the Hudson, Boreas, Schroon, and Cedar Rivers, and Trout Brook (not the same Trout Brook mentioned above). They originate in the southern High Peaks Region and in the low mountains south of the High Peaks Region, flow generally southward, and drain most of the southern half of the county.

Figure 7.—The primary drainage systems of Essex County, New York: The Lake Champlain—St. Lawrence River system drains north and the Hudson River drains south.

A very small portion of the county (about 3 percent) lies within the Raquette River watershed which drains northwest into the St. Lawrence River. The principal sub-basin of the Raquette watershed that lies in Essex County is the Cold River basin. The Cold River originates in the southern High Peaks Region and flows generally westward into the Raquette River north of Long Lake.

Water Supply

Victor Putman, Director of the Essex County Department of Community Development and Planning, prepared this section.

Essex County contains 147 NYS Health Department regulated water supplies. There are 36 community (municipal) water supplies, and 111 non-community water supplies (group camps, restaurants, campgrounds, etc.). The majority of water systems (132) utilize groundwater where the remainder (15) utilizes surface water resources. The majority of groundwater supplies are of excellent quality and yield, although several communities are considered to have groundwater under the direct influence of surface water including Port Kent WD #1 and Westport Water Districts. The Westport water system recently installed major improvements as well as filtration facilities; whereas, the Port Kent Water System is currently exploring the potential for a groundwater supply. There are three known large groundwater aquifers within the county including those in the towns of Lewis, Schroon/North Hudson, and the Saranac Lake region. The municipal water supplier in Schroon and Lewis are currently utilizing these aquifers as integral components to their respective community water systems. While the Village of Saranac Lake currently utilizes the surface water resources of McKenzie Pond, the community lost its filtration avoidance and will be seeking a potential groundwater supply source. Of the total county residents in the 2000 census, 38,851 people, approximately 24,000 are served by municipal water supplies, while the remainder uses private drilled wells or springs. The quality of groundwater within most areas of the county is excellent except for isolated bedrock wells paralleling Lake Champlain where natural sulfur deposits have adversely affected water quality. Essex County also has one of the few filtration wavered community water supplies in New York State, namely the Village of Ticonderoga system which uses Gooseneck Pond as its source. This surface water impoundment is located on NYS Forest Preserve Lands and lacks any shoreline development contributing to its excellent water quality. Other regional public surface water supplies including Lake George, Lake Champlain, and Lake Placid have maintained excellent water quality, however emerging manmade contaminants may require more expensive treatment in the future or may require conversion to groundwater supplies as development and wastewater treatment discharges compromise surface water quality.

Soil Temperature Regimes

Temperature data from well water, air, and soil indicate three soil temperature zones within Essex County. The distribution of mesic, frigid, and cryic soil types is shown in figure 8.

Mesic soils are generally mapped from 95 feet in elevation (mean Lake Champlain lake level) to 500 feet above sea level. Frigid soils are mapped from 500 to 3,000 feet in elevation, and cryic soils are mapped above 3,000 feet.

A soil with a frigid temperature regime is warmer in summer than a soil with a cryic regime, but its mean annual temperature is lower than 8 degrees C (47 degrees F), and the difference between mean summer (June, July, and August) and mean winter (December, January, and February) soil temperatures is more than 6 degrees C (43 degrees F) either at a depth of 50 cm (20 inches) from the soil surface, or at bedrock or a dense-layer contact, whichever is shallower. A soil with a mesic temperature regime has a mean annual soil temperature 8 degrees C or higher, but lower than 15

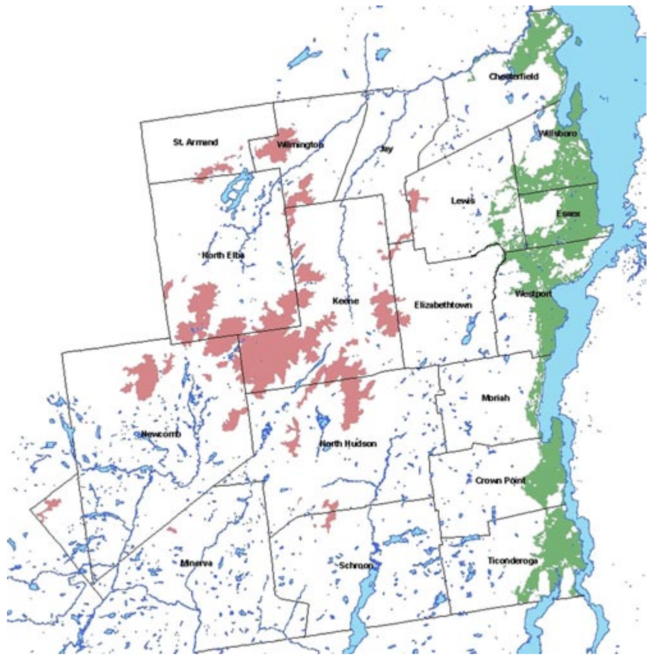

Figure 8.—Temperature data from well water, air, and soil indicate three soil temperature zones in Essex County. The distribution of mesic, frigid, and cryic soils is illustrated above. Areas in green are mesic, areas in coral are cryic, and the remainder and bulk of the county is frigid.

degrees C (59 degrees F), and the difference between mean summer and mean winter soil temperatures is more than 6 degrees C at a depth of 50 cm from the soil surface.

The estimated break between mesic, frigid, and cryic soil temperature regimes in Essex County was based on three sources of data:

1. Soil temperature estimates from 9 well water temperature measurements (dug and drilled wells) during 1985 to help establish the mesic/frigid division.
2. Soil temperature estimates based on average air temperature measurements plus 2 degrees F from 1971 through 2000: Peru, NY 45.1 degrees F; Elizabethtown 43.6; Lake Placid 40.9; Newcomb 40.7 degrees F, and Mount Mansfield, VT 34.4 degrees F.
3. Soil temperature measurements using resistance readings of thermocouples that were installed at 20 inches below the surface. Monthly readings during the growing season were collected during 1991 through 1993 at 9 sites on Whiteface Mountain, representing elevations from 2,200 to 4,400 feet above sea level to help establish the frigid/cryic division.

Climate

This section was prepared by the Natural Resources Conservation Service National Water and Climate Center, Portland, Oregon.

Climate Tables are created from climate stations Peru (Clinton County), Elizabethtown, Lake Placid 2 S, Newcomb 3 E, New York (all in Essex County), as well as from nearby Mt. Mansfield, Vermont. In addition, new mean annual precipitation and temperature maps from official USDA-NRCS climate maps of New York, developed using Oregon State University's PRISM system, were used in this analysis.

Thunderstorm days, relative humidity, percent sunshine, and wind information are estimated from First Order station Burlington, Vermont.

Table 1 gives data on temperature and precipitation for the survey area as recorded at these climate stations in the period 1971 to 2000. Table 2 shows probable dates of the first freeze in fall and the last freeze in spring. Table 3 provides data on the length of the growing season.

In winter, average temperatures at Peru 2 WSW, Elizabethtown, Lake Placid, Newcomb, and Mt. Mansfield are 21.2, 19.2, 18.1, 17.4 and 11.8 degrees F, respectively. Average daily minimum temperatures in winter are 11.6, 7.9, 7.3, 6.7 and 4.0 degrees, respectively. The lowest temperatures on record are -34 at Peru 2 WSW on January 27, 1994; -35 degrees at Elizabethtown on January 15, 1957; -37 degrees at Lake Placid on February 11, 1979; -34 degrees at Newcomb on January 19, 1997; and -40 at Mt. Mansfield on December 31, 1962.

In summer, average temperatures are 67.6, 66.3, 62.2, 62.5 and 56.3 degrees, respectively, at Peru 2 WSW, Elizabethtown, Lake Placid, Newcomb, and Mt. Mansfield. Average daily maximum temperatures in summer are 79.1, 79.1, 74.4, 74.5 and 63.4 degrees, respectively. The highest temperatures ever recorded were 100 degrees at Peru 2 WSW on July 20, 1977; 102 degrees at Elizabethtown on July 18, 1953; 97 degrees at Lake Placid on July 19, 1953; 94 at Newcomb on August 3, 1988; and 84 at Mt. Mansfield on June 7, 1999.

Growing degree days are shown in table 1. They are equivalent to “heat units”. During the month, growing degree days accumulate by the amount that the average temperature each day exceeds a base temperature (40 degrees F). The normal monthly accumulation is used to schedule single or successive plantings of a crop between the last freeze in spring and the first freeze in fall.

Average annual precipitation over Essex County ranges from 34 to 40 inches over eastern sections to between 40 and 48 inches over higher terrain in the west, including around 70 inches on Mt. Marcy at 5,344 feet based on PRISM spatial climate estimates (fig. 9). Mean annual precipitation at the four climate stations is 30.99 inches at Peru 2 WSW, 36.89 inches at Elizabethtown, 39.65 inches at Lake Placid, 42.40 inches at Newcomb, and 78.78 inches at Mt. Mansfield. Of this, about 45 to 51 percent usually falls in May through September growing season (at lower elevations). The heaviest 1-day precipitation amounts during the periods of record were: 5.70 inches at Peru 2WSW on June 16, 1987; 3.80 inches at Elizabethtown on September 17, 1999; 4.27 inches at Lake Placid on this same date; 3.96 inches at Newcomb on September 6, 1985; and 9.92 inches at Mt. Mansfield, also on September 17, 1999. Thunderstorms occur on about 23 days each year, and most occur in July.

Average seasonal snowfall is also highly dependent on elevation, with about 60 inches falling annually along Lake Champlain, and as much as 150 inches or more over the highest terrain, including near Mt. Marcy. At the climate stations used here the annual averages are 58.1, 65.0, 115.2, 112.0 and 217.4 inches, respectively, at Peru 2 WSW, Elizabethtown, Lake Placid, Newcomb and Mt. Mansfield. The greatest snow depths at any one time during the periods of record were: 44 inches at Peru 2 WSW on February 17, 1954; 47 inches at Elizabethtown, recorded on January 22, 1978; 47 inches at Lake Placid, recorded on March 8, 1971; 53 inches at Newcomb, recorded on March 8, 1971; and 149 inches at Mt. Mansfield, recorded on April 2, 1969. On average, about 75 days per year have at least 1 inch of snow on the ground near Lake Champlain, but western parts of the county average around 140 days, and the highest mountains see snow on the ground about 180 to 200 days per year, on average. The heaviest 1-day snowfalls on record were: 28.0 inches at Peru 2 WSW on March 6, 2001, 27.0 inches at Elizabethtown on March 7, 2001; 18.0 inches at Lake Placid on December 12, 1952 (the snow record only extends through 1986 at Lake Placid); 20.0 inches at Newcomb on March 14, 1993; and 24.0 inches at Mt. Mansfield on November 18, 1965.

The average relative humidity in mid-afternoon is about 70 percent in winter and about 55 percent in summer. Humidity is higher at night, and the average at dawn is about 75 percent in winter and spring, and about 85 percent in late summer and early

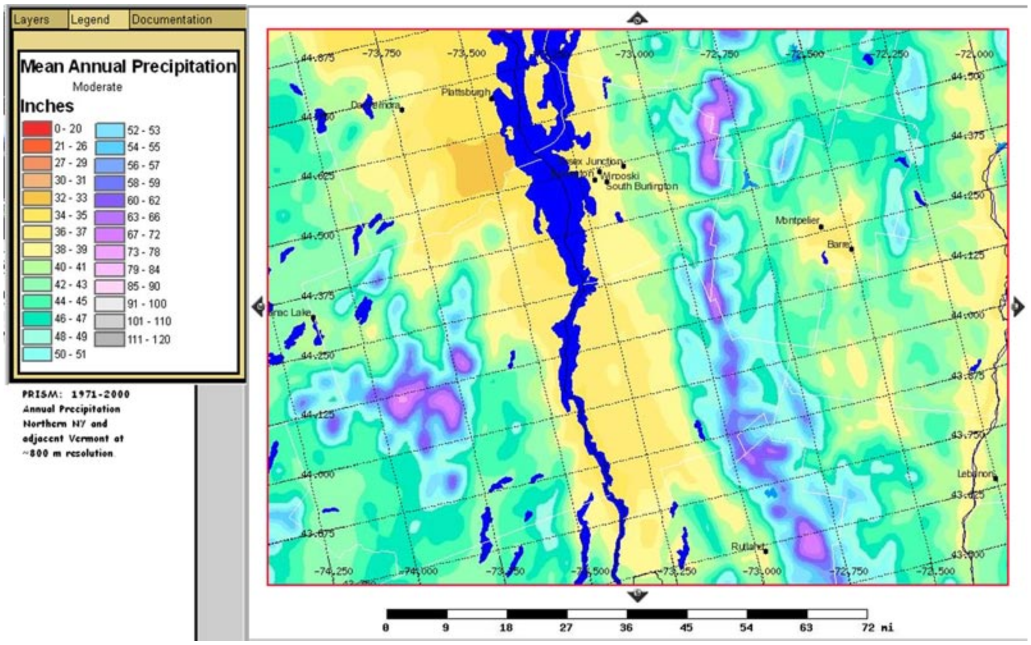

Figure 9.—PRISM: 1971 – 2000 Annual Precipitation Northern NY and adjacent Vermont.

fall. The sun shines about 62 percent of the time in summer and about 40 percent in winter. The prevailing wind is from the south at lower elevations, especially near Lake Champlain, but is from the west at higher elevations. Average wind speed is highest in the winter and spring, when it is about 10 miles per hour in the valleys, but averages about 30 mph on the higher ridges near Mt. Marcy.

How This Survey Was Made

This survey was made to provide information about the soils and miscellaneous areas in the survey area. The information includes a description of the soils and miscellaneous areas and their location and a discussion of their suitability, limitations, and management for specified uses. Soil scientists observed the steepness, length, and shape of the slopes; the general pattern of drainage; the kinds of crops and native plants; and the kinds of bedrock. They dug many holes to study the soil profile, which is the sequence of natural layers, or horizons, in a soil. The profile extends from the surface down into the unconsolidated material in which the soil formed. The unconsolidated material is devoid of roots and other living organisms and has not been changed by other biological activity.

The soils and miscellaneous areas in the survey area are in an orderly pattern that is related to the geology, landforms, relief, climate, and natural vegetation of the area. Each kind of soil and miscellaneous area is associated with a particular kind of landform or with a segment of the landform. By observing the soils and miscellaneous areas in the survey area and relating their position to specific segments of the landform, a soil scientist develops a concept or model of how they were formed. Thus, during mapping, this model enables the soil scientist to predict with a considerable degree of accuracy the kind of soil or miscellaneous area at a specific location on the landscape.

Commonly, individual soils on the landscape merge into one another as their characteristics gradually change. To construct an accurate soil map, however, soil scientists must determine the boundaries between the soils. They can observe only a limited number of soil profiles. Nevertheless, these observations, supplemented by an understanding of the soil-vegetation-landscape relationship, are sufficient to verify

predictions of the kinds of soil in an area and to determine the boundaries.

Soil scientists recorded the characteristics of the soil profiles that they studied. They noted soil color, texture, size and shape of soil aggregates, kind and amount of rock fragments, distribution of plant roots, reaction, and other features that enable them to identify soils. After describing the soils in the survey area and determining their properties, the soil scientists assigned the soils to taxonomic classes (units). Taxonomic classes are concepts. Each taxonomic class has a set of soil characteristics with precisely defined limits. The classes are used as a basis for comparison to classify soils systematically. Soil taxonomy, the system of taxonomic classification used in the United States, is based mainly on the kind and character of soil properties and the arrangement of horizons within the profile. After the soil scientists classified and named the soils in the survey area, they compared the individual soils with similar soils in the same taxonomic class in other areas so that they could confirm data and assemble additional data based on experience and research.

While a soil survey is in progress, samples of some of the soils in the area generally are collected for laboratory analyses and for engineering tests. Soil scientists interpret the data from these analyses and tests as well as the field-observed characteristics and the soil properties to determine the expected behavior of the soils under different uses. Interpretations for all of the soils are field tested through observation of the soils in different uses and under different levels of management. Some interpretations are modified to fit local conditions, and some new interpretations are developed to meet local needs. Data are assembled from other sources, such as research information, production records, and field experience of specialists. For example, data on crop yields under defined levels of management are assembled from farm records and from field or plot experiments on the same kinds of soil.

Predictions about soil behavior are based not only on soil properties but also on such variables as climate and biological activity. Soil conditions are predictable over long periods of time, but they are not predictable from year to year. For example, soil scientists can predict with a fairly high degree of accuracy that a given soil will have a high water table within certain depths in most years, but they cannot predict that a high water table will always be at a specific level in the soil on a specific date.

After soil scientists located and identified the significant natural bodies of soil in the survey area, they drew the boundaries of these bodies on aerial photographs and identified each as a specific map unit. Aerial photographs show trees, buildings, fields, roads, and rivers, all of which help in locating boundaries accurately.

This survey area was mapped at two levels of detail (fig. 10). At the more detailed level, map units are narrowly defined. Map unit boundaries were plotted and verified at closely spaced intervals. Maps were made at a scale of 1:24,000 or 2,000 feet to the inch, and the allowable minimum size of a soil delineation is 5 to 7 acres (Order 2 soil survey). With the detailed level of mapping, intensive land use planning and management can be achieved such as farmland conservation and residential subdivision planning. At the less detailed level, map units are broadly defined. Boundaries were plotted and verified at wider intervals. Maps were made at a scale of 1:62.500 or 5,208 feet to the inch, and the allowable minimum size of a soil delineation is 40 acres (Order 3 soil survey). With the less detailed level of mapping, extensive land use planning and management is possible such as forest management and watershed planning. In the legend for the detailed soil maps, narrowly defined units are indicated by symbols in which all the characters are alphabetical. For broadly defined units, the first two or three characters are numeric and the last character is alphabetical.

Survey Procedures

The general procedures followed in making this soil survey are described in the National Soil Survey Handbook (USDA-Natural Resources Conservation Service) of

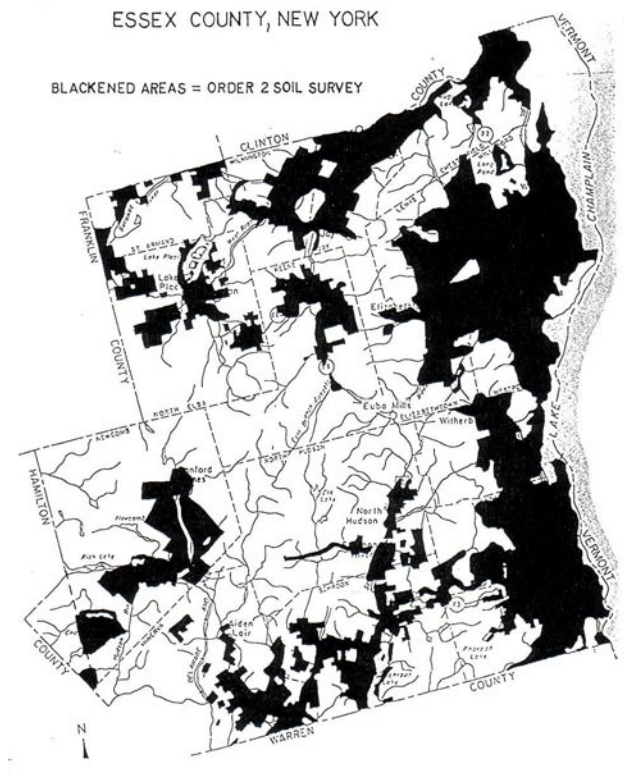

Figure 10.—Areas of the county mapped at the more detailed level (Order 2 – blackened areas), and less detailed level (Order 3), are illustrated above. Order 2 mapping corresponds to New York State Adirondack Park Agency zoning designations of Hamlet, moderate intensity use, low intensity use, rural use, industrial use, and intensive use state land.

the Natural Resources Conservation Service and the Soil Survey Manual (Soil Survey Division Staff, 1993). Soil scientists utilized existing soil information for conservation planning on individual farms prior to the start of the project, as well as soils information collected during special prior mapping projects such as the Soil Survey of the Lake Placid Area, New York (USDA Soil Conservation Service, 1978). Geologic references were also used including “Pleistocene Geology of the Northeast Adirondack Region, New York” (Denny, 1974).

Before field work began, preliminary boundaries of slopes and landforms were plotted stereoscopically on aerial photographs taken in 1968 and 1974. Two map scales were used for the survey. All New York State owned land (except state land zoned “intensive use”) and privately owned land zoned “Resource Management” by the New York State Adirondack Park Agency, was mapped on aerial photos at a scale of 1:62,500. All other areas of the county were mapped on aerial photos with a scale of 1:24,000. Color infrared aerial photographs were employed about 1989 by soil scientists taken from flights in 1985 and 1986. Soil scientists also studied U.S. Geological Survey topographic maps, at a scale of 1:24,000, to relate landform, slope, and image features to the area of survey. Commonly, a reconnaissance was made by vehicle to examine road cuts and surface features before the landscape was traversed on foot.

Sample areas were selected to represent the major landscapes in the county. These areas were investigated to determine soil-landform relationships, diversity of soil types

within landforms, and other data related to land use interpretations. Field notes and profile descriptions were taken to document soil series and map units. As mapping progressed, these preliminary notes were used to define map unit composition. In areas where phases of Vergennes, Amenia, Windsor, and Occum soils are mapped near Lake Champlain, and in other areas of complex soil patterns, traverses were about 100 yards apart. In areas where phases of Becket, Tunbridge, and Monadnock soils are mapped in the Adirondack Upland, where soil patterns are more predictable or relatively simple, traverses were about one quarter mile apart.

As the traverses were made, soil scientists divided the landscape into landforms or landform segments based on use and management of the soils. For example, a hill would be separated from a depression, and a gently sloping summit from a very steep back slope of a ridge. In most areas, soil examinations along the traverses were made 100 to 500 yards apart, depending on the landscape and soil pattern.

Observations of such items as landform, blown-down trees, vegetation, road cuts, animal burrows, stoniness, and bedrock outcrops were made without regard to spacing. Soil boundaries were determined on the basis of soil examinations, observations, and photo interpretation. Soil material was examined with the aid of a hand auger and a spade to a depth of 4 to 6 feet, or to bedrock within a depth of 6 feet. The pedons described as typical were observed and studied in pits that were dug with shovels or backhoes.

Samples for chemical and physical analyses and for analyses of engineering properties were taken from representative sites of several of the soils in the survey area. Most of this sampling occurred between 1984 and 1994. The chemical and physical analyses were made by the Soil Characterization Laboratory, Department of Soil, Crop, and Atmospheric Sciences at Cornell University, Ithaca, New York and by the National Soil Survey Laboratory, Natural Resources Conservation Service, at Lincoln, Nebraska. The results of the analyses are stored in computerized data files at the respective laboratories. The analyses for engineering properties were made by the New York State Department of Transportation, Soil Mechanics Bureau. A description of the laboratory procedures can be obtained on request from the respective laboratories. The results of the studies can be obtained from Cornell University, the New York State Department of Transportation, and the state office of the Natural Resources Conservation Service, Syracuse, New York.

Detailed Soil Map Units

The map units delineated on the detailed soil maps in this survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions in this section, along with the maps, can be used to determine the suitability and potential of a unit for specific uses. They also can be used to plan the management needed for those uses.

A map unit delineation on a soil map represents an area dominated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soils. Within a taxonomic class there are precisely defined limits for the properties of the soils. On the landscape, however, the soils are natural phenomena, and they have the characteristic variability of all natural phenomena. Thus, the range of some observed properties may extend beyond the limits defined for a taxonomic class. Areas of soils of a single taxonomic class rarely, if ever, can be mapped without including areas of other taxonomic classes. Consequently, every map unit is made up of the soils or miscellaneous areas for which it is named and some minor components that belong to taxonomic classes other than those of the major soils.

Most minor soils have properties similar to those of the dominant soil or soils in the map unit, and thus they do not affect use and management. These are called noncontrasting, or similar, components. They may or may not be mentioned in a particular map unit description. Other minor components, however, have properties and behavioral characteristics divergent enough to affect use or to require different management. These are called contrasting, or dissimilar, components. They generally are in small areas and could not be mapped separately because of the scale used. Some small areas of strongly contrasting soils or miscellaneous areas are identified by a special symbol on the maps. The contrasting components are mentioned in the map unit descriptions. A few areas of minor components may not have been observed, and consequently they are not mentioned in the descriptions, especially where the pattern was so complex that it was impractical to make enough observations to identify all the soils and miscellaneous areas on the landscape.

The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into landforms or landform segments that have similar use and management requirements. The delineation of such segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, however, onsite investigation is needed to define and locate the soils and miscellaneous areas.

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives the principal hazards and limitations to be considered in planning for specific uses.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer, slope, stoniness, degree of erosion, and other characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly

indicates a feature that affects use or management. For example, Vergennes silty clay loam, 3 to 8 percent slopes is a phase of the Vergennes series.

Some map units are made up of two or more major soils or miscellaneous areas. These map units are complexes.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. CoB-Chatfield-Hollis complex, 3 to 8 percent slopes, very rocky, very stony is an example.

This survey includes *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock Outcrop is an example.

The detailed soil map units are designated by one of two formats within the legend:

Broadly Defined Legend—Map symbols consist of numbers followed by a letter (e.g., 375A, 721C). The numbers in the symbol represent the soil. The letter, always a capital, indicates the slope: A, B, C, D, and F. This part of the legend is in numerical order.

Narrowly Defined Legend—Map symbols consist of letters (e.g., AmB, MmF, WoA). The first letter, always a capital, is the initial letter of the soil name. The second letter is lower case and separates map units except for slope phases. The third letter, always a capital, indicates the slope: A, B, C, D, E, and F. This part of the legend is in alphabetical order.

Table 4 gives the acreage and proportionate extent of each map unit. Other tables give properties of the soils and the limitations, capabilities, and potentials for many uses. The Glossary defines many of the terms used in describing the soils or miscellaneous areas.

The reaction for organic horizons in the following map unit descriptions is given as a CaCl2 based pH and the reaction for mineral soil horizons is given as H2O based pH.

10A—Pleasant Lake-Burnt Vly complex, 0 to 2 percent slopes

Setting

This broadly defined map unit consists of soils that are mucky, very deep, nearly level, and very poorly drained. They are on bogs and swamps in the Adirondack Upland. Areas range from 10 to 230 acres in size.

Map Unit Composition

Major Components
Pleasant Lake: 45 percent
Burnt Vly: 30 percent

Inclusions
Rumney: 5 percent
Searsport: 5 percent
Tahawus: 5 percent
Bucksport: 4 percent
Unnamed: 3 percent
Wonsqueak: 3 percent

The poorly drained Rumney, Tahawus, Searsport, Bucksport, and Wonsqueak soils may be included in areas of this map unit. Also included are organic soils with higher woody fragment content. Rumney soils are on small flood plain areas near streams, and are loamy. Tahawus soils are on small areas underlain by sandy till. Searsport soils are on small areas underlain by sandy outwash. Bucksport and

Wonsqueak soils occupy similar positions, but have a higher pH. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
  Pleasant Lake: yes
  Burnt Vly: yes
Hydrologic group:
  Pleasant Lake: B/D
  Burnt Vly: B/D

Soil Properties and Qualities

Pleasant Lake
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
  Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: not rated
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material
Reaction (pH):
  0 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
  4 to 5 inches: ultra acid or extremely acid (1.8 to 4.4)
  5 to 9 inches: ultra acid or extremely acid (1.8 to 4.4)
  9 to 31 inches: ultra acid or extremely acid (1.8 to 4.4)
  31 to 44 inches: ultra acid or extremely acid (1.8 to 4.4)
  44 to 53 inches: ultra acid or extremely acid (1.8 to 4.4)
  53 to 66 inches: ultra acid or extremely acid (1.8 to 4.4)
Permeability:
  0 to 4 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  4 to 5 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  5 to 9 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  9 to 31 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  31 to 44 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  44 to 53 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  53 to 66 inches: moderately slow to rapid (0.2 to 20 inches/hour)

Burnt Vly
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
  Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high

Shrink-swell potential: low
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material over sandy glaciofluvial deposits
Reaction (pH):
0 to 10 inches: ultra acid to very strongly acid (1.8 to 4.5)
10 to 15 inches: ultra acid to very strongly acid (1.8 to 4.5)
15 to 24 inches: ultra acid to very strongly acid (1.8 to 4.5)
24 to 34 inches: ultra acid to very strongly acid (1.8 to 4.5)
34 to 56 inches: extremely acid to slightly acid (3.5 to 6.5)
56 to 72 inches: extremely acid to slightly acid (3.5 to 6.5)
Permeability:
0 to 10 inches: moderately slow to rapid (0.2 to 20 inches/hour)
10 to 15 inches: moderately slow to rapid (0.2 to 20 inches/hour)
15 to 24 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
24 to 34 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
34 to 56 inches: moderate to very rapid (0.6 to 100 inches/hour)
56 to 72 inches: moderate to very rapid (0.6 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland

- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of soils with thick organic surfaces should be avoided when locating haul roads.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Areas of soils with thick organic surfaces should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome the windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The organic matter content limits soil strength and severely affects the capacity of these soils to bear a load without movement.

- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields

- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets

- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.

13A—Burnt Vly-Rumney-Pleasant Lake complex, 0 to 2 percent slopes

Setting

This broadly defined map unit consists of soils that are mucky and loamy, very deep, nearly level, and very poorly drained to poorly drained (fig. 11). They are on bogs in the Adirondack Upland. Areas range from 5 to 830 acres in size.

Map Unit Composition

Major Components
Burnt Vly: 40 percent
Rumney: 30 percent
Pleasant Lake: 20 percent

Inclusions
Searsport: 3 percent
Tahawus: 3 percent
Fluvaquents-Udifluvents: 1 percent
Podunk: 1 percent
Unnamed: 1 percent
Wonsqueak: 1 percent

The Searsport, Tahawus, somewhat poorly drained and well drained Fluvaquents-Udifluvents, moderately well drained Podunk and Wonsqueak soils may be included in areas of this map unit. Also included are organic soils with higher woody fragment content. Searsport soils are on small areas underlain by sandy outwash. Tahawus soils are on small areas underlain by sandy till. Fluvaquents-Udifluvents soils occupy positions directly adjacent to stream channels. Podunk soils occupy higher flood plain positions than Rumney soils. Wonsqueak soils occupy similar positions as Burnt Vly soils, but have a higher pH. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w

Figure 11.—Oblique aerial view of an area of Burnt Vly-Rumney-Pleasant Lake complex north of Boreas Ponds in the town of North Hudson. Adjacent to the open water in several places, mucky soils underlie areas of brownish-looking emergent wetland plants and lighter green areas of Black Spruce–Tamarack bog. Poorly drained loamy alluvial soils lie along the edges of the streams entering the wetland and form small levees.

Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: bogs
Parent material: organic material over sandy glaciofluvial deposits
Reaction (pH):
- 0 to 10 inches: ultra acid to very strongly acid (1.8 to 4.5)
- 10 to 15 inches: ultra acid to very strongly acid (1.8 to 4.5)
- 15 to 24 inches: ultra acid to very strongly acid (1.8 to 4.5)
- 24 to 34 inches: ultra acid to very strongly acid (1.8 to 4.5)
- 34 to 56 inches: extremely acid to slightly acid (3.5 to 6.5)
- 56 to 72 inches: extremely acid to slightly acid (3.5 to 6.5)

Permeability:
- 0 to 10 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 10 to 15 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 15 to 24 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 24 to 34 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 34 to 56 inches: moderate to very rapid (0.6 to 100 inches/hour)
- 56 to 72 inches: moderate to very rapid (0.6 to 100 inches/hour)

Rumney
Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
- Water table kind: apparent

Flooding: frequent
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: flood plains
Parent material: loamy alluvium derived from gneiss
Reaction (pH):
- 0 to 7 inches: very strongly acid to neutral (4.5 to 7.3)
- 7 to 12 inches: very strongly acid to neutral (4.5 to 7.3)
- 12 to 19 inches: very strongly acid to neutral (4.5 to 7.3)
- 19 to 30 inches: very strongly acid to neutral (4.5 to 7.3)
- 30 to 33 inches: very strongly acid to neutral (4.5 to 7.3)
- 33 to 48 inches: very strongly acid to neutral (4.5 to 7.3)
- 48 to 54 inches: very strongly acid to neutral (4.5 to 7.3)
- 54 to 72 inches: very strongly acid to neutral (4.5 to 7.3)

Permeability:
- 0 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 30 to 33 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 33 to 48 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 48 to 54 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 54 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Pleasant Lake
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
- Water table kind: apparent

Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: not rated
Surface runoff potential: negligible
Landform: bogs
Parent material: organic material

Reaction (pH):
- 0 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
- 4 to 5 inches: ultra acid or extremely acid (1.8 to 4.4)
- 5 to 9 inches: ultra acid or extremely acid (1.8 to 4.4)
- 9 to 31 inches: ultra acid or extremely acid (1.8 to 4.4)
- 31 to 44 inches: ultra acid or extremely acid (1.8 to 4.4)
- 44 to 53 inches: ultra acid or extremely acid (1.8 to 4.4)
- 53 to 66 inches: ultra acid or extremely acid (1.8 to 4.4)

Permeability:
- 0 to 4 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 4 to 5 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 5 to 9 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 9 to 31 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 31 to 44 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 44 to 53 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 53 to 66 inches: moderately slow to rapid (0.2 to 20 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland
- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Areas of soils with thick organic surfaces should be avoided when locating haul roads.
- Avoid constructing log landings on frequently flooded soils.
- Areas of soils with thick organic surfaces should be avoided when locating log landings.
- Avoid timber harvesting during months of seasonal saturation. Harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome the windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to ponding, flooding, or seasonal high water tables. Consult the Forestland Productivity table “Trees to Manage” section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The organic matter content limits soil strength and severely affects the capacity of these soils to bear a load without movement.

- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.

29C—Burnt Vly-Colton-Rumney complex, 0 to 15 percent slopes

Setting

This broadly defined map unit consists of soils that are mucky, sandy and gravelly, and loamy, very deep, nearly level to strongly sloping, and very poorly drained, excessively drained, and poorly drained respectively. They are on flood plains and outwash plains in the Adirondack Upland. Areas range from 30 to 1,020 acres in size.

Map Unit Composition

Major Components
Burnt Vly: 40 percent

Colton: 30 percent
Rumney: 20 percent

Inclusions
Fluvaquents-Udifluvents: 3 percent
Adams: 2 percent
Pleasant Lake: 2 percent
Podunk: 2 percent
Unnamed: 1 percent

The somewhat poorly drained and well drained Fluvaquents-Udifluvents, somewhat excessively drained Adams, Pleasant Lake, and moderately well drained Podunk soils may be included in areas of this map unit. Also included are sandy and gravelly soils that are moderately well drained. Fluvaquents-Udifluvents soils occupy positions directly adjacent to stream channels. Podunk soils occupy higher flood plain positions than Rumney soils. Adams soils occupy similar positions as Colton soils, but have less gravel. Pleasant Lake soils occupy similar positions as Burnt Vly soils, but are greater than 51 inches to mineral soil material. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
  Burnt Vly: yes
  Colton: no
  Rumney: yes
Hydrologic group:
  Burnt Vly: B/D
  Colton: A
  Rumney: B/D

Soil Properties and Qualities

Burnt Vly
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
  Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material over sandy glaciofluvial deposits
Reaction (pH):
  0 to 10 inches: ultra acid to very strongly acid (1.8 to 4.5)
  10 to 15 inches: ultra acid to very strongly acid (1.8 to 4.5)
  15 to 24 inches: ultra acid to very strongly acid (1.8 to 4.5)
  24 to 34 inches: ultra acid to very strongly acid (1.8 to 4.5)
  34 to 56 inches: extremely acid to slightly acid (3.5 to 6.5)
  56 to 72 inches: extremely acid to slightly acid (3.5 to 6.5)

Permeability:
- 0 to 10 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 10 to 15 inches: moderately slow to rapid (0.2 to 20 inches/hour)
- 15 to 24 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 24 to 34 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
- 34 to 56 inches: moderate to very rapid (0.6 to 100 inches/hour)
- 56 to 72 inches: moderate to very rapid (0.6 to 100 inches/hour)

Colton
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: outwash plains
Parent material: gravelly outwash derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
- 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
- 3 to 6 inches: extremely acid to moderately acid (3.5 to 6.0)
- 6 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
- 13 to 21 inches: extremely acid to moderately acid (3.5 to 6.0)
- 21 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 2 to 3 inches: rapid or very rapid (6 to 100 inches/hour)
- 3 to 6 inches: rapid or very rapid (6 to 100 inches/hour)
- 6 to 13 inches: rapid or very rapid (6 to 100 inches/hour)
- 13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
- 21 to 72 inches: very rapid (20 to 100 inches/hour)

Rumney
Drainage class: poorly drained
Depth to bedrock: greater than 60 inches

48 to 54 inches: moderately rapid to very rapid (2 to 100 inches/hour)
54 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads due to wetness.
- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Areas of poorly drained and very poorly drained soils should be avoided when locating log landings.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Limiting timber harvesting operations to winter months when the ground is frozen is recommended for soils with thick organic surfaces and low bearing strength.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness.
- Seeding cut and fill areas after grading and leveling and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability due to strongly sloping areas in areas of Colton soils.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in Colton soils. Consult the Forestland Productivity table “Trees to Manage” section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.
- The slope influences the use of machinery and the ease of excavation in Colton soils. Special building practices and designs may be required to ensure satisfactory performance.
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- Because of ponding, some areas of these soils are very limited as a site for septic tank absorption fields.
- The excessive rate of fluid movement through some areas of these soils limits the proper treatment of effluent from septic systems. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Probable flooding in some areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- The seasonal high water table in some areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Some areas of these soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of some areas of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture in some areas of these soils. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of some areas of these soils.

- The slope of some areas of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.

113A—Ondawa-Rumney complex, 0 to 3 percent slopes

Setting

This broadly defined map unit consists of soils that are loamy, very deep, nearly level, and well and poorly drained respectively. They are on flood plains in the Adirondack Upland. Areas range from 10 to 420 acres in size.

Map Unit Composition

Major Components
Ondawa: 45 percent
Rumney: 30 percent

Inclusions
Burnt Vly: 5 percent
Lovewell: 5 percent
Podunk: 5 percent
Charles: 4 percent
Croghan: 3 percent
Fluvaquents-Udifluvents: 1 percent
Naumburg: 1 percent
Unnamed: 1 percent

The very poorly drained Burnt Vly, the moderately well drained Lovewell and Podunk, Charles, moderately well drained Croghan, somewhat poorly drained and well drained Fluvaquents-Udifluvents, and somewhat poorly drained Naumburg soils may be included in areas of this map unit. Also included are very poorly drained loamy flood plain soils. Burnt Vly soils are on small depressions and are mucky. Lovewell and Podunk soils occupy slightly lower positions on the flood plain than Ondawa soils, and Lovewell soils are silty. Charles soils occupy similar positions as Rumney soils but are silty. Croghan and Naumburg soils are on small areas underlain by sandy outwash. Fluvaquents-Udifluvents soils occupy positions directly adjacent to stream channels. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: prime farmland

- 0 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 30 to 33 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 33 to 48 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 48 to 54 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 54 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland

- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness in some areas of these soils.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness in some areas of these soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard in some areas of these soils.
- Selective harvesting systems that minimize canopy openings and reduce root system damage, and maintenance of buffers around the upland edges may help overcome the windthrow hazard caused by wetness in some areas of these soils.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness in some areas of these soils. Consult the Forestland Productivity table “Trees to Manage” section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development

- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements

- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement in some areas of these soils. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in some areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of some areas of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

123A—Lovewell-Cornish complex, 0 to 2 percent slopes

Setting

This broadly defined map unit consists of soils that are silty, very deep, nearly level, and moderately well drained and somewhat poorly drained respectively. They are on flood plains in the Adirondack Upland. Areas range from 60 to 80 acres in size.

Map Unit Composition

Major Components
Lovewell: 45 percent
Cornish: 30 percent

Inclusions
Charles: 5 percent
Medomak: 5 percent
Podunk: 5 percent
Rumney: 4 percent
Hailesboro: 3 percent
Fluvaquents-Udifluvents: 2 percent
Unnamed: 1 percent

The poorly drained Charles, very poorly drained Medomak, Podunk, poorly drained Rumney, Hailesboro, and somewhat poorly drained and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Also included are well drained silty flood plain soils. Charles, Medomak, and Rumney soils occupy lower positions, and Rumney soils are loamy. Podunk soils occupy similar positions as Lovewell soils, but are loamy. Hailesboro soils occupy similar positions as Cornish soils, but are silty and clayey. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: prime farmland

    12 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    21 to 35 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

35 to 42 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
42 to 48 inches: moderate to rapid (0.6 to 20 inches/hour)
48 to 53 inches: moderate to rapid (0.6 to 20 inches/hour)
53 to 72 inches: moderate to rapid (0.6 to 20 inches/hour)

Use and Management

Woodland

- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species in areas of Cornish soils will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table “Trees to Manage” section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements

- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.

- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

350B—Duxbury fine sandy loam, 3 to 15 percent slopes, very stony

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, very deep, gently sloping to strongly sloping, and well drained. It is on summits of outwash terraces in the Adirondack Upland. Areas range from 20 to 300 acres in size.

Map Unit Composition

Major Components
Duxbury, very stony: 85 percent

Inclusions
Colton: 4 percent
Adams: 3 percent
Champlain: 2 percent
Becket: 1 percent
Croghan: 1 percent
Fernlake: 1 percent
Monadnock: 1 percent
Sunapee: 1 percent
Unnamed: 1 percent

The excessively drained Colton, somewhat excessively drained Adams, Champlain and Fernlake, Becket and Monadnock, and moderately well drained Croghan and Sunapee soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton, Adams, and Champlain soils occupy similar positions, but Colton soils are sandy and gravelly, Adams and Champlain soils are sandy, and Champlain soils lack a spodic horizon. Becket, Fernlake, and Monadnock soils are on small areas underlain by till, and Fernlake soils are sandy. Croghan soils are in small depressions and are sandy. Sunapee soils are on small depressions and are underlain by till. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
Duxbury, very stony: no
Hydrologic group:
Duxbury, very stony: A

Soil Properties and Qualities

Duxbury, very stony
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate to high
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: low
Surface fragment cover: very stony
Landform: outwash terraces
Parent material: loamy lacustrine deposits over gravelly outwash derived from gneiss
Reaction (pH):
0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 4 inches: extremely acid to slightly acid (3.5 to 6.5)
4 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
5 to 13 inches: extremely acid to slightly acid (3.5 to 6.5)
13 to 21 inches: extremely acid to slightly acid (3.5 to 6.5)
21 to 31 inches: very strongly acid to slightly acid (4.5 to 6.5)
31 to 36 inches: very strongly acid to slightly acid (4.5 to 6.5)
36 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
21 to 31 inches: very rapid (20 to 100 inches/hour)
31 to 36 inches: very rapid (20 to 100 inches/hour)
36 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

363A—Adams loamy sand, 0 to 3 percent slopes

Setting

This broadly defined map unit consists of soils that are sandy, very deep, nearly level, and somewhat excessively drained. It is on summits of deltas, kame terraces, outwash plains in the Adirondack Upland. Areas range from 30 to 160 acres in size.

Map Unit Composition

Major Components
Adams: 75 percent

Inclusions
Colton: 5 percent
Duxbury: 5 percent
Croghan: 3 percent
Champlain: 2 percent
Fernlake: 2 percent
Monadnock: 2 percent
Naumburg: 2 percent
Nicholville: 2 percent
Unnamed: 2 percent

The excessively drained Colton, well drained Duxbury and Monadnock, moderately well drained Croghan and Nicholville, Champlain, Fernlake, and somewhat poorly drained Naumburg soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton, Duxbury, and Champlain soils occupy similar positions, but Colton soils are sandy and gravelly; Duxbury soils are loamy over gravelly or sandy; and Champlain soils lack a spodic horizon. Fernlake and Monadnock soils occupy similar positions, but are on small areas underlain by till, and Monadnock soils are loamy over sandy or gravelly. Croghan, Naumburg, and Nicholville soils are on small depressions and Nicholville soils are silty. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3s
Hydric soil rating:
    Adams: no
Hydrologic group:
    Adams: A

Soil Properties and Qualities

Adams
Drainage class: somewhat excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: deltas, kame terraces, outwash plains
Parent material: sandy glaciolacustrine deposits derived from gneiss
Reaction (pH):
    0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
    2 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
    4 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
    5 to 8 inches: very strongly acid to moderately acid (4.5 to 6.0)
    8 to 14 inches: very strongly acid to moderately acid (4.5 to 6.0)
    14 to 23 inches: very strongly acid to moderately acid (4.5 to 6.0)
    23 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
    0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
    2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    4 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
    5 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
    8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
    14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
    23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment

of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

363B—Adams loamy sand, 3 to 15 percent slopes

Setting

This broadly defined map unit consists of soils that are sandy, very deep, gently to strongly sloping, and somewhat excessively drained. It is on summits, shoulders, and backslopes of deltas, kame terraces, and outwash plains in the Adirondack Upland. Areas range from 15 to 190 acres in size.

Map Unit Composition

Major Components
Adams: 75 percent

Inclusions
Colton: 5 percent
Duxbury: 5 percent
Champlain: 3 percent
Nicholville: 3 percent
Croghan: 2 percent
Fernlake: 2 percent
Monadnock: 2 percent
Unnamed: 2 percent
Naumburg: 1 percent

The excessively drained Colton, well drained Duxbury and Monadnock, moderately well drained Croghan and Nicholville, Champlain, Fernlake, and somewhat poorly drained Naumburg soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton, Duxbury, and Champlain soils occupy similar positions, but Colton soils are sandy and gravelly, Duxbury soils are loamy over gravelly or sandy, and Champlain soils lack a spodic horizon. Fernlake and Monadnock soils occupy similar positions, but are on small areas underlain by till, and Monadnock soils are loamy over sandy or gravelly. Croghan, Naumburg, and Nicholville soils are on small depressions, and Nicholville soils are silty. Included areas can occupy about 25 percent of this unit.

14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and re-seeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

363F—Adams loamy sand, 35 to 60 percent slopes

Setting

This broadly defined map unit consists of soils that are sandy, very deep, very steep, and somewhat excessively drained. It is on backslopes of deltas, kame terraces, outwash plains in the Adirondack Upland. Areas range from 35 to 240 acres in size.

Sunapee: 3 percent
Unnamed: 1 percent

The somewhat excessively drained Adams, Hailesboro, very poorly drained Searsport, Mooers, Roundabout, and Sunapee soils may be included in areas of this map unit. Also included are areas of poorly drained sandy soils. Adams soils occupy higher positions. Mooers and Sunapee soils occupy similar positions as Croghan soils, but Mooers soils lack a spodic horizon, and Sunapee soils are loamy. Hailesboro and Roundabout soils occupy similar positions as Naumburg soils, but Hailesboro soils are silty and clayey, and Roundabout soils are silty. Searsport soils are on depressions and drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance

  Croghan: no
Hydrologic group:
  Naumburg: A/D
  Croghan: A/D

Soil Properties and Qualities

Naumburg
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: apparent
Flooding: none

Available water capacity: low to moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Landform: deltas, outwash plains, stream terraces
Parent material: sandy glaciolacustrine deposits derived from gneiss
Reaction (pH):
0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 7 inches: extremely acid to strongly acid (3.5 to 5.5)
7 to 10 inches: extremely acid to strongly acid (3.5 to 5.5)
10 to 18 inches: extremely acid to strongly acid (3.5 to 5.5)
18 to 31 inches: extremely acid to strongly acid (3.5 to 5.5)
31 to 54 inches: very strongly acid to slightly acid (4.5 to 6.5)
54 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
0 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
2 to 7 inches: rapid (6 to 20 inches/hour)
7 to 10 inches: rapid (6 to 20 inches/hour)
10 to 18 inches: rapid (6 to 20 inches/hour)
18 to 31 inches: rapid (6 to 20 inches/hour)
31 to 54 inches: rapid or very rapid (6 to 100 inches/hour)
54 to 72 inches: rapid or very rapid (6 to 100 inches/hour)

Croghan
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
Water table kind: apparent
Flooding: none
Available water capacity: low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very low
Landform: deltas, outwash plains, stream terraces
Parent material: sandy glaciolacustrine deposits derived from gneiss
Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
5 to 8 inches: very strongly acid to moderately acid (4.5 to 6.0)
8 to 14 inches: very strongly acid to moderately acid (4.5 to 6.0)
14 to 23 inches: very strongly acid to moderately acid (4.5 to 6.0)
23 to 29 inches: very strongly acid to moderately acid (4.5 to 6.0)
29 to 42 inches: very strongly acid to moderately acid (4.5 to 6.0)
42 to 45 inches: very strongly acid to moderately acid (4.5 to 6.0)
45 to 72 inches: very strongly acid to moderately acid (4.5 to 6.0)
Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
3 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
5 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 29 inches: moderately rapid to very rapid (2 to 100 inches/hour)

29 to 42 inches: moderately rapid to very rapid (2 to 100 inches/hour)
42 to 45 inches: moderately rapid to very rapid (2 to 100 inches/hour)
45 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland
- Locating roads in areas of better drained soils, avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads due to seasonal wetness.
- Applying gravel base material during construction of haul roads will help overcome limitations due to sandy surface layers.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Applying gravel base material to log landings during construction and operation will help overcome limitations caused by sandy surfaces.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Maintaining a vegetative cover or spreading slash over exposed soil areas will help overcome harvest equipment operability limitations caused by sandy surfaces.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome the windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems are advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

367A—Searsport-Haplosaprists-Naumburg complex, 0 to 3 percent slopes

Setting

This broadly defined map unit consists of soils that are sandy and mucky, very deep, nearly level, and very poorly drained and somewhat poorly drained respectively. They are on deltas, outwash plains, stream terraces, and bogs in the Adirondack Upland. Areas range from 10 to 380 acres in size.

Map Unit Composition

Major Components
Searsport: 40 percent
Haplosaprists: 30 percent
Naumburg: 20 percent

Inclusions
Croghan: 2 percent
Roundabout: 2 percent
Rumney: 2 percent
Wegatchie: 2 percent
Tahawus: 1 percent
Unnamed: 1 percent

The moderately well drained Croghan, Roundabout, poorly drained Rumney and Wegatchie, and Tahawus soils may be included in areas of this map unit. Also included are areas of poorly drained sandy soils. Croghan soils occupy higher positions. Roundabout soils occupy similar positions as Naumburg soils, but are silty. Wegatchie soils occupy slightly lower positions than Naumburg soils, and are silty and clayey. Rumney soils occupy small flood plain positions adjacent to streams and are loamy. Tahawus soils occupy similar positions as Searsport and Haplosaprists soils, but are on small areas underlain by till. Included areas can occupy about 10 percent of this unit.

54 to 72 inches: rapid or very rapid (6 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads due to wetness.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.

- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to ponding, flooding, or general wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- Subsidence of the organic material reduces the load bearing capacity of these soils.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The SeA and 367A map units have components with textures below 40 inches that are finer than typical for the range of the Searsport series.

This should not significantly affect use and management on a local basis for most purposes.

375A—Colton-Adams complex, 0 to 3 percent slopes

Setting

This broadly defined map unit consists of soils that are gravelly and sandy, very deep, nearly level, and excessively drained and somewhat excessively drained respectively. It is on summits of kame terraces and outwash plains in the Adirondack Upland. Areas range from 20 to 235 acres in size.

Map Unit Composition

Major Components
Colton: 45 percent
Adams: 30 percent

Inclusions
Duxbury: 5 percent
Monadnock: 5 percent
Unnamed: 5 percent
Croghan: 4 percent
Hermon: 3 percent
Champlain: 2 percent
Fernlake: 1 percent

The well drained Duxbury and Monadnock, moderately well drained Croghan, Hermon, Champlain, and Fernlake soils may be included in areas of this map unit. Also included are gravelly areas that are moderately well drained. Duxbury and Champlain soils occupy similar positions, but Duxbury soils are loamy over gravelly or sandy, and Champlain soils lack a spodic horizon. Fernlake, Hermon and Monadnock soils occupy similar positions, but are on small areas underlain by till, and Monadnock soils are loamy over sandy or gravelly. Croghan soils are on small depressions. Included areas can occupy about 25 percent of this unit.

14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

- Applying gravel base material during construction of haul roads will help overcome limitations due to sandy surface layers.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

375C—Colton-Adams complex, 3 to 15 percent slopes

Setting

This broadly defined map unit consists of soils that are gravelly and sandy, very deep, gently to strongly sloping, and excessively drained and somewhat excessively drained respectively. It is on shoulders and backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 10 to 360 acres in size.

Map Unit Composition

8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Applying gravel base material during construction of haul roads will help overcome limitations due to sandy surface layers.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

375D—Colton-Adams complex, 15 to 35 percent slopes

Setting

This broadly defined map unit consists of soils that are gravelly and sandy, very deep, moderately steep and steep, and excessively drained and somewhat excessively drained respectively. It is on backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 20 to 415 acres in size.

Adams: 30 percent

Inclusions
Duxbury: 5 percent
Monadnock: 5 percent
Unnamed: 5 percent
Fernlake: 4 percent
Hermon: 3 percent
Champlain: 2 percent
Croghan: 1 percent

The well drained Duxbury and Monadnock, moderately well drained Croghan, Hermon, Champlain, and Fernlake soils may be included in areas of this map unit. Also included are gravelly areas that are moderately well drained. Duxbury and Champlain soils occupy similar positions, but Duxbury soils are loamy over gravelly or sandy, and Champlain soils lack a spodic horizon. Fernlake, Hermon and Monadnock soils occupy similar positions, but are on small areas underlain by till, and Monadnock soils are loamy over sandy or gravelly. Croghan soils are on drainageways. Included areas can occupy about 25 percent of this unit.

- 23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.

- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

375F—Colton-Adams complex, 35 to 60 percent slopes

Setting

This broadly defined map unit consists of soils that are gravelly and sandy, very deep, very steep, and excessively drained and somewhat excessively drained respectively. It is on backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 35 to 415 acres in size.

Use and Management

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.

- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

649C—Monadnock-Tunbridge-Tahawus complex, 0 to 15 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, loamy, and sandy, very deep to moderately deep, gently sloping to strongly sloping, and well drained or very poorly drained. It is on summits, shoulders, backslopes, and toeslopes of hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 610 acres in size.

Map Unit Composition

Major Components
Monadnock, rocky, very bouldery: 40 percent
Tunbridge, rocky, very bouldery: 30 percent
Tahawus, very bouldery: 20 percent

Inclusions
Becket: 2 percent
Lyman: 2 percent
Adirondack: 1 percent
Burnt Vly: 1 percent
Knob Lock: 1 percent
Rock outcrop: 1 percent
Sunapee: 1 percent
Unnamed: 1 percent

The Becket, Lyman, and Knob Lock, moderately well drained Sunapee, somewhat poorly drained Adirondack, and Burnt Vly soils may be included in areas of this map unit. Also included are areas of mineral soils that are very shallow to bedrock.

Becket, Lyman, and Knob Lock soils occupy similar positions as Monadnock and Tunbridge soils, but Becket soils have a dense substratum, Lyman soils are shallow, and Knob Lock soils are organic and very shallow to shallow. Sunapee soils occupy slightly lower positions than Monadnock soils. Adirondack soils occupy slightly higher positions than Tahawus soils, and have a dense substratum. Burnt Vly soils occupy similar positions as Tahawus soils but are mucky. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

9 to 17 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
17 to 24 inches: moderately rapid to very rapid (2 to 100 inches/hour)
24 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads and log landings in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness in some areas of these soils.

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness in some areas.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard in some areas of these soils.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness in some areas of these soils.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness in some areas of these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- The depth to bedrock and hardness of the bedrock in some areas of these soils greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The seasonal high water table severely limits the capacity of some areas of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Because of the potential for ponding, some areas of these soils are very limited as a site for dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata in some areas of these soils may limit the proper treatment of the effluent from septic systems. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- The somewhat limited depth to bedrock in some areas of these soils reduces the filtering capacity and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Because of ponding, some areas of these soils are very limited as a site for septic tank absorption fields.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- Depth to hard bedrock in some areas of these soils may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Some areas of these soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.

650C—Monadnock-Adams-Colton complex, 3 to 15 percent slopes, bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, sandy, and gravelly, very deep, gently sloping to strongly sloping, and well drained, somewhat excessively drained, and excessively drained respectively. It is on shoulders and backslopes of kame moraines in the Adirondack Upland. Areas range from 20 to 550 acres in size.

Map Unit Composition

Major Components

Monadnock, bouldery: 40 percent
Adams: 30 percent
Colton: 20 percent

Inclusions

Duxbury: 2 percent
Unnamed: 2 percent
Becket: 1 percent
Croghan: 1 percent
Fernlake: 1 percent
Naumburg: 1 percent
Nicholville: 1 percent
Sunapee: 1 percent

The Duxbury, Becket, moderately well drained Croghan, Sunapee, and Nicholville, Fernlake, and somewhat poorly drained Naumburg soils may be included in areas of this map unit. Also included are areas that have a very bouldery surface. Duxbury, Becket, and Fernlake soils occupy similar positions, but Becket soils have a dense substratum. Croghan, Sunapee, and Nicholville soils occupy slightly lower positions, and Nicholville soils are silty. Naumburg soils are on small depressions or drainageways. Included areas can occupy about 10 percent of this unit.

 14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
 23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Colton
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: kame moraines
Parent material: gravelly outwash derived from gneiss
Reaction (pH):
 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
 3 to 6 inches: extremely acid to moderately acid (3.5 to 6.0)
 6 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
 13 to 21 inches: extremely acid to moderately acid (3.5 to 6.0)
 21 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
 1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
 2 to 3 inches: rapid or very rapid (6 to 100 inches/hour)
 3 to 6 inches: rapid or very rapid (6 to 100 inches/hour)
 6 to 13 inches: rapid or very rapid (6 to 100 inches/hour)
 13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
 21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Woodland

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability due to strongly sloping areas.
- Applying gravel base material during construction of haul roads will help overcome limitations due to sandy surface layers.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in Colton and Adams soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata in some areas of these soils may limit the proper treatment of the effluent from septic systems. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- The excessive rate of fluid movement through some areas of these soils limits the proper treatment of effluent from septic systems. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action in areas of Monadnock soils, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

650D—Monadnock-Adams-Colton complex, 15 to 35 percent slopes, bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, sandy, and gravelly, very deep, moderately steep and steep, and well drained, somewhat excessively drained, and excessively drained respectively. It is on backslopes of kame moraines in the Adirondack Upland. Areas range from 15 to 610 acres in size.

Map Unit Composition

Major Components
Monadnock, bouldery: 40 percent
Adams: 30 percent
Colton: 20 percent

Inclusions
Duxbury: 2 percent
Unnamed: 2 percent
Becket: 1 percent
Croghan: 1 percent
Fernlake: 1 percent
Naumburg: 1 percent
Nicholville: 1 percent
Sunapee: 1 percent

The Duxbury and Becket, moderately well drained Croghan, Sunapee, and Nicholville, Fernlake, and somewhat poorly drained Naumburg soils may be included in areas of this map unit. Also included are areas that have a very bouldery surface. Duxbury, Becket, and Fernlake soils occupy similar positions, but Becket soils have a dense substratum. Croghan, Sunapee, and Nicholville soils occupy slightly lower positions, and Nicholville soils are silty. Naumburg soils are on drainageways. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in Colton and Adams soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata in some areas of these soils may limit the proper treatment of the effluent from septic systems. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.

- The excessive rate of fluid movement through some areas of these soils limits the proper treatment of effluent from septic systems. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action in some areas of these soils, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

651D—Monadnock-Tunbridge complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, and loamy, very deep to moderately deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 3,400 acres in size.

Map Unit Composition

Major Components
Monadnock, rocky, very bouldery: 45 percent
Tunbridge, rocky, very bouldery: 30 percent

Inclusions
Becket: 5 percent
Fernlake: 5 percent
Knob Lock: 5 percent
Lyman: 5 percent
Sunapee: 3 percent
Rock outcrop: 1 percent
Unnamed: 1 percent

The Becket, Lyman, and Knob Lock, somewhat excessively drained Fernlake, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas of mineral soils that are very shallow to bedrock. Becket, Lyman, Knob Lock, and Fernlake soils occupy similar positions, but Becket soils have a dense substratum, Lyman soils are shallow, Knob Lock soils are organic and very shallow to shallow, and Fernlake soils are sandy. Sunapee soils are on drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

4 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
7 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
18 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 inches, bedrock

Use and Management

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads due to steep slopes.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations due to moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata in these soils may limit the proper treatment of the effluent from septic systems in

some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- The somewhat limited depth to bedrock in some areas reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- Depth to hard bedrock in Tunbridge soils may limit site preparation such as shaping and grading and restrict installation of roads and streets.

653C—Monadnock fine sandy loam, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, very deep, gently sloping to strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 15 to 410 acres in size.

Map Unit Composition

Major Components
Monadnock, very bouldery: 85 percent

Inclusions
Becket: 5 percent
Adams: 2 percent
Colton: 2 percent
Fernlake: 2 percent
Sunapee: 2 percent
Hermon: 1 percent
Unnamed: 1 percent

The Becket, somewhat excessively drained Adams, Fernlake, and Hermon, excessively drained Colton, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Adams, Colton, Fernlake, and Hermon soils occupy similar positions, but Becket soils have a dense substratum, Adams and Colton soils are underlain by sandy and gravelly outwash, and Fernlake and Hermon soils are sandy. Sunapee soils occupy slightly lower positions. Included areas can occupy about 15 percent of this unit.

Use and Management

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.

- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations due to very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

655B—Sunapee-Monadnock complex, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, very deep, gently sloping to strongly sloping, and moderately well drained to well

drained. It is on backslopes and footslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 20 to 360 acres in size.

Map Unit Composition

Major Components
Sunapee, very bouldery: 45 percent
Monadnock, very bouldery: 30 percent

Inclusions
Adirondack: 5 percent
Becket: 5 percent
Fernlake: 5 percent
Adams: 4 percent
Skerry: 3 percent
Unnamed: 3 percent

The Becket, somewhat excessively drained Adams and Fernlake, Skerry, and somewhat poorly drained Adirondack soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Adams, and Fernlake soils occupy similar positions as Monadnock soils, but Becket soils have a dense substratum, Adams soils are underlain by sandy outwash, and Fernlake soils are sandy. Skerry soils occupy similar positions as Sunapee soils, but have a dense substratum. Adirondack soils are on depressions and drainageways and have a dense substratum. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Sunapee, very bouldery: no
  Monadnock, very bouldery: no
Hydrologic group:
  Sunapee, very bouldery: B
  Monadnock, very bouldery: A

Soil Properties and Qualities

Sunapee, very bouldery
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: moderate to high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
  4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
  5 to 7 inches: extremely acid to strongly acid (3.5 to 5.5)
  7 to 14 inches: extremely acid to strongly acid (3.5 to 5.5)

14 to 19 inches: extremely acid to strongly acid (3.5 to 5.5)
19 to 31 inches: extremely acid to strongly acid (3.5 to 5.5)
31 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)
Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
7 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
19 to 31 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
31 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Monadnock, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate to high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till over sandy ablation till derived from gneiss
Reaction (pH):
0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
3 to 12 inches: extremely acid to moderately acid (3.5 to 6.0)
12 to 19 inches: extremely acid to moderately acid (3.5 to 6.0)
19 to 30 inches: extremely acid to moderately acid (3.5 to 6.0)
30 to 37 inches: extremely acid to moderately acid (3.5 to 6.0)
37 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)
Permeability:
0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation in some areas of these soils, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard. Consult the Water Features table for months of seasonal saturation.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness in some areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table in some areas severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table in Sunapee soils impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

657C—Monadnock-Tahawus complex, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, and sandy, very deep, gently sloping to strongly sloping, and well drained or very poorly drained. It is on shoulders, backslopes, and toeslopes of till plains in the Adirondack Upland. Areas range from 20 to 1,205 acres in size.

Map Unit Composition

Major Components
Monadnock, very bouldery: 60 percent
Tahawus, very bouldery: 30 percent

Inclusions
Adirondack: 2 percent
Burnt Vly: 2 percent
Sunapee: 2 percent
Adams: 1 percent
Becket: 1 percent
Colton: 1 percent
Unnamed: 1 percent

The somewhat poorly drained Adirondack, Burnt Vly, moderately well drained Sunapee, somewhat excessively drained Adams, Becket, and excessively drained Colton soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adirondack soils occupy slightly higher positions than Tahawus soils and have dense substratum. Burnt Vly soils occupy similar positions as Tahawus soils but are mucky. Sunapee soils occupy slightly lower positions than Monadnock soils. Becket, Adams, and Colton soils occupy similar positions as Monadnock soils, but Becket soils have a dense substratum, and Adams and Colton soils are underlain by sandy and gravelly outwash. Included areas can occupy about 10 percent of this unit.

  24 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland

- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Locating roads on better drained soils or limiting road construction to drier parts of the year in some areas of these soils will help overcome construction limitations of haul roads due to wetness.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness in some areas of these soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard in some areas of these soils.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness in some areas of these soils.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness in some areas of these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- Because of the potential for ponding, some areas of these soils are very limited as a site for dwellings with basements.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas.

Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Because of ponding, some areas of these soils are very limited as a site for septic tank absorption fields.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- Some areas of these soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.

657D—Monadnock-Tahawus complex, 15 to 35 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy over sandy or gravelly, and sandy, very deep, moderately steep and steep, and well drained or very poorly drained. It is on backslopes and toeslopes of till plains in the Adirondack Upland. Areas range from 40 to 400 acres in size.

Map Unit Composition

Major Components
Monadnock, very bouldery: 60 percent
Tahawus, very bouldery: 30 percent

Inclusions
Adams: 2 percent
Becket: 2 percent
Unnamed: 2 percent
Adirondack: 1 percent
Burnt Vly: 1 percent
Colton: 1 percent
Sunapee: 1 percent

The somewhat excessively drained Adams, Becket, somewhat poorly drained Adirondack, Burnt Vly, excessively drained Colton, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Adams, and Colton soils occupy similar positions as Monadnock soils, but Becket soils have a dense substratum, and Adams and Colton soils are underlain by sandy and gravelly outwash. Adirondack soils occupy slightly

higher positions than Tahawus soils and have a dense substratum. Burnt Vly soils occupy similar positions as Tahawus soils but are mucky. Sunapee soils occupy slightly lower positions than Monadnock soils. Included areas can occupy about 10 percent of this unit.

24 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Locating roads on better drained soils or limiting road construction to drier parts of the year in some areas of these soils will help overcome construction limitations of haul roads caused by wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment

operability limitations caused by wetness in some areas of these soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges in some areas of these soils may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness in some areas of these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.
- Because of the potential for ponding, some areas of these soils are very limited as a site for dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Because of ponding, some areas of these soils are very limited as a site for septic tank absorption fields.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- Some areas of these soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.

661C—Hermon gravelly loamy sand, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are sandy and gravelly, very deep, gently sloping to strongly sloping, and somewhat excessively drained. It is on backslopes, shoulders, and summits of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 15 to 325 acres in size.

Map Unit Composition

Major Components
Hermon, very bouldery: 85 percent

Inclusions
Monadnock: 4 percent
Colton: 3 percent
Fernlake: 3 percent
Becket: 2 percent
Adams: 1 percent
Sunapee: 1 percent
Unnamed: 1 percent

The well drained Monadnock and Becket, excessively drained Colton, Fernlake, Adams, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Monadnock, Fernlake, Becket, Colton, and Adams soils occupy similar positions, but Monadnock soils are loamy over gravelly or sandy, Fernlake soils have less rock fragments, Becket soils are loamy, and Colton and Adams soils are underlain by sandy and gravelly outwash. Sunapee soils occupy slightly lower positions and are loamy. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Hermon, very bouldery: no
Hydrologic group:
  Hermon, very bouldery: A

Soil Properties and Qualities

Hermon, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: low
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: sandy and gravelly ablation till derived from gneiss

Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
- 3 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
- 5 to 10 inches: extremely acid to moderately acid (3.5 to 6.0)
- 10 to 20 inches: extremely acid to moderately acid (3.5 to 6.0)
- 20 to 29 inches: strongly acid or moderately acid (5.1 to 6.0)
- 29 to 38 inches: strongly acid or moderately acid (5.1 to 6.0)
- 38 to 72 inches: strongly acid or moderately acid (5.1 to 6.0)

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 5 to 10 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 10 to 20 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 20 to 29 inches: very rapid (20 to 100 inches/hour)
- 29 to 38 inches: very rapid (20 to 100 inches/hour)
- 38 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

661D—Hermon gravelly loamy sand, 15 to 35 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are sandy and gravelly, very deep, moderately steep and steep, and somewhat excessively drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 25 to 240 acres in size.

Map Unit Composition

Major Components
Hermon, very bouldery: 85 percent

Inclusions
Monadnock: 4 percent
Colton: 3 percent
Fernlake: 3 percent
Adams: 2 percent
Becket: 2 percent
Unnamed: 1 percent

The well drained Monadnock and Becket, excessively drained Colton, Fernlake, and Adams soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Monadnock, Fernlake, Becket, Colton, and Adams soils occupy similar positions, but Monadnock soils are loamy over gravelly or sandy, Fernlake soils have less rock fragments, Becket soils are loamy, and Colton and Adams soils are underlain by sandy and gravelly outwash. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

- 3 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 5 to 10 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 10 to 20 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 20 to 29 inches: very rapid (20 to 100 inches/hour)
- 29 to 38 inches: very rapid (20 to 100 inches/hour)
- 38 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

661F—Hermon gravelly loamy sand, 35 to 60 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are sandy and gravelly, very deep, very steep, and somewhat excessively drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 20 to 130 acres in size.

Map Unit Composition

Major Components
Hermon, very bouldery: 85 percent

Inclusions
Monadnock: 4 percent
Colton: 3 percent
Fernlake: 3 percent
Adams: 2 percent
Becket: 2 percent
Unnamed: 1 percent

The well drained Monadnock and Becket, excessively drained Colton, Fernlake, and Adams soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Monadnock, Fernlake, Becket, Colton, and Adams soils occupy similar positions, but Monadnock soils are loamy over gravelly or sandy, Fernlake soils have less rock fragments, Becket soils are loamy, and Colton and Adams soils are underlain by sandy and gravelly outwash. Included areas can occupy about 25 percent of this unit.

If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

705B—Adirondack-Tahawus complex, 0 to 8 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy and sandy, very deep, nearly level to gently sloping, and somewhat poorly drained or very poorly drained. It is on toeslopes and footslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 10 to 825 acres in size.

Map Unit Composition

Major Components
Adirondack, very bouldery: 40 percent
Tahawus, very bouldery: 35 percent

Inclusions
Burnt Vly: 5 percent
Skerry: 5 percent
Sunapee: 5 percent
Rumney: 4 percent
Unnamed: 3 percent
Ampersand: 2 percent
Wilmington: 1 percent

The Burnt Vly, moderately well drained Skerry and Sunapee, poorly drained Rumney, and Ampersand and Wilmington soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Burnt Vly soils occupy similar positions as Tahawus soils but are mucky. Skerry and Sunapee soils occupy slightly higher positions than Adirondack soils, but Sunapee soils lack the dense substratum. Rumney soils occupy small flood plain deposits adjacent to streams. Ampersand and Wilmington soils have higher organic matter content. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Adirondack, very bouldery: no
  Tahawus, very bouldery: yes
Hydrologic group:
  Adirondack, very bouldery: C/D
  Tahawus, very bouldery: B/D

Soil Properties and Qualities

Adirondack, very bouldery
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 38 inches to densic material
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
  4 to 6 inches: extremely acid to strongly acid (3.5 to 5.5)
  6 to 8 inches: extremely acid to strongly acid (3.5 to 5.5)
  8 to 9 inches: extremely acid to strongly acid (3.5 to 5.5)
  9 to 18 inches: extremely acid to strongly acid (3.5 to 5.5)
  18 to 26 inches: very strongly acid to moderately acid (4.5 to 6.0)
  26 to 34 inches: strongly acid or moderately acid (5.1 to 6.0)
  34 to 43 inches: strongly acid or moderately acid (5.1 to 6.0)
  43 to 72 inches: strongly acid or moderately acid (5.1 to 6.0)
Permeability:
  0 to 2 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  2 to 4 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  4 to 6 inches: moderate (0.6 to 2 inches/hour)
  6 to 8 inches: moderate (0.6 to 2 inches/hour)
  8 to 9 inches: moderate (0.6 to 2 inches/hour)
  9 to 18 inches: moderate (0.6 to 2 inches/hour)
  18 to 26 inches: moderate (0.6 to 2 inches/hour)
  26 to 34 inches: slow (0.06 to 0.2 inches/hour)

34 to 43 inches: slow (0.06 to 0.2 inches/hour)
43 to 72 inches: slow (0.06 to 0.2 inches/hour)

Tahawus, very bouldery
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: sandy till derived from gneiss
Reaction (pH):
0 to 2 inches: extremely acid to strongly acid (3.5 to 5.5)
2 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
5 to 9 inches: extremely acid to strongly acid (3.5 to 5.5)
9 to 17 inches: very strongly acid to slightly acid (4.5 to 6.5)
17 to 24 inches: moderately acid to neutral (5.6 to 7.3)
24 to 72 inches: moderately acid to neutral (5.6 to 7.3)
Permeability:
0 to 2 inches: moderately slow to rapid (0.2 to 20 inches/hour)
2 to 5 inches: moderately slow to rapid (0.2 to 20 inches/hour)
5 to 9 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
9 to 17 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
17 to 24 inches: moderately rapid to very rapid (2 to 100 inches/hour)
24 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.

- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Because of the potential for ponding, some areas of these soils are very limited as a site for dwellings with basements.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Because of ponding, some areas of these soils are very limited as a site for septic tank absorption fields.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Some areas of these soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

721C—Becket-Tunbridge-Skerry complex, 3 to 15 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep to moderately deep, gently sloping to strongly sloping, and well drained or moderately well drained. It is on backslopes and shoulders of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 790 acres in size.

Map Unit Composition

Major Components
Becket, rocky, very bouldery: 40 percent
Tunbridge, rocky, very bouldery: 30 percent
Skerry, rocky, very bouldery: 20 percent

Inclusions
Adirondack: 2 percent
Lyman: 2 percent
Monadnock: 2 percent
Rock outcrop: 2 percent
Unnamed: 2 percent

The somewhat poorly drained Adirondack, and Lyman and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adirondack soils occupy lower positions than Skerry soils. Lyman and Monadnock soils occupy similar positions as Becket and Tunbridge soils, but Lyman soils are shallow, and Monadnock soils lack a dense substratum. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
- Becket, rocky, very bouldery: no
- Tunbridge, rocky, very bouldery: no
- Skerry, rocky, very bouldery: no

Hydrologic group:

Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 4 inches: extremely acid to slightly acid (3.5 to 6.5)
  4 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 15 inches: extremely acid to slightly acid (3.5 to 6.5)
  15 to 26 inches: extremely acid to slightly acid (3.5 to 6.5)
  26 to 38 inches: extremely acid to slightly acid (3.5 to 6.5)
  38 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 15 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  15 to 26 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  26 to 38 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  38 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads due to seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.

- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations due to very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils and seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The seasonal high water table severely limits the capacity of some areas of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock in some areas reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- Depth to hard bedrock in some areas may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- The seasonal high water table in some areas impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

721D—Becket-Tunbridge complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep to moderately deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 2,410 acres in size.

Map Unit Composition

Major Components
Becket, rocky, very bouldery: 45 percent
Tunbridge, rocky, very bouldery: 30 percent

Inclusions
Lyman: 8 percent
Monadnock: 8 percent
Knob Lock: 3 percent
Skerry: 2 percent
Unnamed: 2 percent
Adirondack: 1 percent
Rock outcrop: 1 percent

The Lyman, Monadnock, and Knob Lock, moderately well drained Skerry, and somewhat poorly drained Adirondack soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Lyman, Monadnock, and Knob Lock soils occupy similar positions, but Lyman soils are shallow, Monadnock soils lack a dense substratum, and Knob Lock soils are organic and very shallow to shallow. Skerry soils occupy slightly lower positions, than Becket soils. Adirondack soils are on drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s

18 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 inches, bedrock

Use and Management

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.

723C—Becket fine sandy loam, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, gently to strongly sloping, and well drained. It is on backslopes and shoulders of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 20 to 730 acres in size.

Map Unit Composition

Major Components

Becket, very bouldery: 85 percent

Inclusions

Skerry: 5 percent
Monadnock: 4 percent
Adirondack: 2 percent
Tunbridge: 2 percent
Unnamed: 2 percent

The moderately well drained Skerry, somewhat poorly drained Adirondack, Monadnock, and Tunbridge soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Skerry soils occupy lower positions. Adirondack soils occupy small depressions and drainageways. Monadnock and Tunbridge soils occupy similar positions, but Monadnock soils lack a dense substratum, and Tunbridge soils are moderately deep to bedrock. Included areas can occupy about 15 percent of this unit.

Use and Management

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10

percent will help overcome construction limitations of haul roads caused by seasonal wetness (fig. 12).
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations due to very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the

Figure 12.—Vigorous forest growth on Becket soils in the town of North Hudson. Note the dark, moist subsoil in the upper part of the road cut. This image, taken in the early spring after snow melt, illustrates the dense lodgment till substratum creating a brief perched water table above its contact with the subsoil. Special care should be taken during timber harvesting operations to protect soils with seasonal high water tables from rutting damage and accelerated erosion.

freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

723D—Becket fine sandy loam, 15 to 35 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 985 acres in size.

Map Unit Composition

Major Components
Becket, very bouldery: 85 percent

Inclusions
Monadnock: 6 percent
Skerry: 4 percent
Tunbridge: 2 percent

Unnamed: 2 percent
Adirondack: 1 percent

The Monadnock, Tunbridge, moderately well drained Skerry, and somewhat poorly drained Adirondack soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Monadnock and Tunbridge soils occupy similar positions, but Monadnock soils lack a dense substratum, and Tunbridge soils are moderately deep to bedrock. Skerry soils occupy lower positions. Adirondack soils are on drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Becket, very bouldery: no
Hydrologic group:
  Becket, very bouldery: B

Soil Properties and Qualities

Becket, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 36 inches to densic material
Depth to seasonal high water table: 30 to 36 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 3 inches: extremely acid to slightly acid (3.5 to 6.5)
  3 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 18 inches: extremely acid to slightly acid (3.5 to 6.5)
  18 to 33 inches: extremely acid to slightly acid (3.5 to 6.5)
  33 to 47 inches: very strongly acid to neutral (4.5 to 7.3)
  47 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
  47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10

percent will help overcome construction limitations of haul roads caused by seasonal wetness.

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

723F—Becket fine sandy loam, 35 to 60 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, very steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 30 to 310 acres in size.

Map Unit Composition

Major Components
Becket, very bouldery: 85 percent

Inclusions
Monadnock: 8 percent
Tunbridge: 3 percent
Unnamed: 3 percent
Skerry: 1 percent

The Monadnock, Tunbridge, and moderately well drained Skerry soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Monadnock and Tunbridge soils occupy similar positions, but Monadnock soils lack a dense substratum, and Tunbridge soils are moderately deep to bedrock. Skerry soils are on drainageways. Included areas can occupy about 15 percent of this unit.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

725B—Skerry-Becket complex, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, gently sloping to strongly sloping, and moderately well drained and well drained. It is on backslopes and footslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 685 acres in size.

Map Unit Composition

Major Components
Skerry, very bouldery: 45 percent
Becket, very bouldery: 30 percent

Inclusions
Adirondack: 9 percent
Sunapee: 7 percent
Unnamed: 4 percent
Tunbridge: 3 percent
Monadnock: 2 percent

The somewhat poorly drained Adirondack, Sunapee, Monadnock, and Tunbridge soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adirondack soils occupy small depressions and drainageways. Sunapee soils occupy similar positions as Skerry soils but lack a dense substratum. Monadnock and Tunbridge soils occupy similar positions as Becket soils, but

Monadnock soils lack a dense substratum, and Tunbridge soils are moderately deep to bedrock. Included areas can occupy about 25 percent of this unit.

Use and Management

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional

wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

727B—Skerry-Adirondack complex, 0 to 8 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, nearly level to gently sloping, and moderately well drained and somewhat poorly drained. It is on backslopes and footslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 1,150 acres in size.

Map Unit Composition

Major Components
Skerry, very bouldery: 45 percent
Adirondack, very bouldery: 30 percent

Inclusions
Becket: 5 percent
Monadnock: 5 percent
Sunapee: 5 percent
Tahawus: 5 percent
Ampersand: 3 percent
Unnamed: 2 percent

The well drained Becket and Monadnock, Sunapee, very poorly drained Tahawus, and Ampersand soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Becket and Monadnock occupy higher positions than Skerry soils, and Monadnock soils lack a dense substratum. Sunapee soils occupy similar positions as Skerry soils, but lack a dense substratum. Tahawus soils are on small depressions and drainageways, and are sandy. Ampersand soils occupy similar positions as Adirondack soils, but have a higher organic matter content. Included areas can occupy about 25 percent of this unit.

Use and Management

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.

- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations due to seasonal wetness. Riparian setbacks should be at least 200 feet.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

831C—Tunbridge-Lyman complex, 3 to 15 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, moderately deep to shallow, gently sloping to strongly sloping, and well drained. It is on summits, shoulders, and backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 490 acres in size.

Map Unit Composition

Major Components
Tunbridge, very rocky, very bouldery: 45 percent
Lyman, very rocky, very bouldery: 30 percent

Inclusions
Becket: 5 percent
Rock outcrop: 5 percent
Monadnock: 4 percent
Skerry: 4 percent
Knob Lock: 3 percent
Rawsonville: 2 percent
Hogback: 1 percent
Unnamed: 1 percent

The Becket, Monadnock, Knob Lock, Rawsonville, Hogback, and moderately well drained Skerry soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Becket, Monadnock, Knob Lock, Rawsonville, and Hogback soils occupy similar positions, but Becket and Monadnock soils are very deep to bedrock, Knob Lock soils are organic, and Rawsonville and Hogback soils have a higher organic matter content. Skerry soils are very deep to bedrock and are on drainageways. Included areas can occupy about 25 percent of this unit.

9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
18 inches, bedrock

Use and Management

Woodland

- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep and shallow soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The somewhat limited depth to bedrock in some areas reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

831D—Tunbridge-Lyman complex, 15 to 35 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, moderately deep to shallow, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 1,455 acres in size.

Map Unit Composition

18 inches, bedrock

Use and Management

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations due to moderately deep and shallow soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations due to very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock in some areas reduces the filtering capacity

of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

831F—Tunbridge-Lyman complex, 35 to 60 percent slopes, very rocky, very bouldery

833C—Tunbridge-Adirondack-Lyman complex, 3 to 15 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep to shallow, gently to strongly sloping, and well and somewhat poorly drained. It is on footslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 20 to 400 acres in size.

Map Unit Composition

Major Components
Tunbridge, very rocky, very bouldery: 40 percent
Adirondack, very rocky, very bouldery: 30 percent
Lyman, very rocky, very bouldery: 20 percent

Inclusions
Rock Outcrop: 3 percent
Knob Lock: 2 percent
Ampersand: 1 percent
Hogback: 1 percent
Monadnock: 1 percent
Rawsonville: 1 percent
Tahawus: 1 percent

The Knob Lock, Ampersand, Hogback, Monadnock, Rawsonville, and very poorly drained Tahawus soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Knob Lock, Ampersand, Hogback, Monadnock, and Rawsonville soils occupy similar positions, but Knob Lock soils are

organic, Ampersand, Rawsonville and Hogback soils have a higher organic matter content, and Monadnock soils are loamy over sandy or gravelly. Tahawus soils occupy lower positions than Adirondack soils and are sandy. Included areas can occupy about 10 percent of this unit.

- 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
- 3 to 9 inches: extremely acid to moderately acid (3.5 to 6.0)
- 9 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
- 13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
- 18 inches, bedrock

Permeability:
- 0 to 0 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)

1 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
18 inches, bedrock

Use and Management

Woodland

- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep and shallow soils.
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during months of seasonal saturation in some areas or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of

excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- The seasonal high water table in some areas severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- The seasonal high water table in some areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity in some areas of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.

851D—Lyman-Knob Lock complex, 15 to 35 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy and organic, shallow to very shallow, moderately steep and steep, and well drained to excessively drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 20 to 350 acres in size.

Map Unit Composition

Major Components
Lyman, very rocky, very bouldery: 45 percent
Knob Lock, very rocky, very bouldery: 30 percent

Inclusions
Tunbridge: 10 percent
Rock outcrop: 5 percent
Hogback: 3 percent
Becket: 2 percent
Hermon: 2 percent
Monadnock: 2 percent
Unnamed: 1 percent

The Tunbridge, Hogback, Becket, Monadnock, and somewhat excessively drained Hermon soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Tunbridge, Becket, Monadnock, Hogback, and Hermon soils occupy similar positions, but Tunbridge soils are moderately deep to bedrock, Becket, Monadnock, and Hermon soils are very deep to bedrock, Hermon soils are sandy, and Hogback soils have a higher organic matter content. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Lyman, very rocky, very bouldery: no
  Knob Lock, very rocky, very bouldery: no
Hydrologic group:
  Lyman, very rocky, very bouldery: D
  Knob Lock, very rocky, very bouldery: D

Soil Properties and Qualities

Lyman, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
  0 to 0 inches: ultra acid or extremely acid (1.8 to 4.4)
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
  3 to 9 inches: extremely acid to moderately acid (3.5 to 6.0)
  9 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
  13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
  18 inches, bedrock

Permeability:
- 0 to 0 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 inches, bedrock

Knob Lock, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 1 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very high
Landform: glaciated hillside or mountainsides
Parent material: non-saturated organic material over loamy till derived from gneiss
Reaction (pH):
- 0 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
- 3 to 7 inches: ultra acid or extremely acid (1.8 to 4.4)
- 7 to 9 inches: extremely acid or very strongly acid (3.5 to 5.0)
- 9 inches, bedrock

Permeability:
- 0 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 3 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 9 inches: moderate to very rapid (0.6 to 100 inches/hour)
- 9 inches, bedrock

Use and Management

Woodland
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic

salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

881F—Rock outcrop-Knob Lock-Lyman complex, 35 to 60 percent slopes, very bouldery

Setting

This broadly defined map unit consists of areas of exposed bedrock and soils that are loamy and organic, shallow to very shallow, very steep, and well drained to excessively drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland (fig. 13). Areas range from 20 to 495 acres in size.

Map Unit Composition

Major Components
Rock outcrop, very bouldery: 40 percent
Knob Lock, very rocky, very bouldery: 30 percent
Lyman, very rocky, very bouldery: 20 percent

Inclusions
Tunbridge: 3 percent
Becket: 2 percent
Hogback: 2 percent
Hermon: 1 percent

Figure 13.—Oblique aerial view, in the town of Schroon, of the Rock Outcrop-Knob Lock-Lyman map unit occupying the very steep upper backslope of this hillside. Note the many landslide scars in the map unit. These areas are probably best managed for wildlife and watershed purposes.

Monadnock: 1 percent
Unnamed: 1 percent

The Tunbridge, Hogback, Becket, Monadnock, and somewhat excessively drained Hermon soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Tunbridge, Becket, Monadnock, Hogback, and Hermon soils occupy similar positions, but Tunbridge soils are moderately deep to bedrock; Becket, Monadnock, and Hermon soils are very deep to bedrock; Hermon soils are sandy; and Hogback soils have a higher organic matter content. Included areas can occupy about 10 percent of this unit.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

930C—Mundalite-Rawsonville-Ampersand complex, 3 to 15 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep to moderately deep, gently sloping to strongly sloping, and well drained or somewhat poorly drained. It is on backslopes and shoulders of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 30 to 490 acres in size.

Map Unit Composition

Major Components
Mundalite, rocky, very bouldery: 40 percent
Rawsonville, rocky, very bouldery: 30 percent
Ampersand, rocky, very bouldery: 20 percent

Inclusions
Becket: 2 percent
Hogback: 2 percent
Knob Lock: 2 percent
Tunbridge: 2 percent
Rock outcrop: 1 percent
Unnamed: 1 percent

The Becket, Hogback, Knob Lock, and Tunbridge soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Tunbridge, Hogback, and Knob Lock soils occupy similar positions, but Becket and Tunbridge soils have lower organic matter content; Hogback soils are shallow to bedrock; and Knob Lock soils are organic and shallow to very shallow to bedrock. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Mundalite, rocky, very bouldery: no
  Rawsonville, rocky, very bouldery: no
  Ampersand, rocky, very bouldery: no
Hydrologic group:
  Mundalite, rocky, very bouldery: C
  Rawsonville, rocky, very bouldery: B
  Ampersand, rocky, very bouldery: B/D

Soil Properties and Qualities

Mundalite, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 25 to 40 inches to densic material
Depth to seasonal high water table: 25 to 40 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium

Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
- 3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
- 5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
- 14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
- 27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
- 37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)

Permeability:
- 0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
- 1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 5 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 14 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 27 to 37 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
- 37 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Rawsonville, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
- 2 to 3 inches: extremely acid to strongly acid (3.5 to 5.5)
- 3 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
- 4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
- 5 to 11 inches: extremely acid to strongly acid (3.5 to 5.5)
- 11 to 20 inches: extremely acid to strongly acid (3.5 to 5.5)
- 20 to 25 inches: extremely acid to strongly acid (3.5 to 5.5)
- 25 inches, bedrock

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 5 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 11 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 20 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 25 inches, bedrock

Ampersand, rocky, very bouldery
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches

Depth to root-restrictive feature: 20 to 40 inches to densic material
Depth to seasonal high water table: 6 to 18 inches
    Water table kind: perched
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
    0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
    1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
    3 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
    4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
    5 to 13 inches: extremely acid to strongly acid (3.5 to 5.5)
    13 to 19 inches: extremely acid to strongly acid (3.5 to 5.5)
    19 to 24 inches: very strongly acid to moderately acid (4.5 to 6.0)
    24 to 32 inches: very strongly acid to moderately acid (4.5 to 6.0)
    32 to 72 inches: very strongly acid to moderately acid (4.5 to 6.0)
Permeability:
    0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
    1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    4 to 5 inches: moderate to rapid (0.6 to 20 inches/hour)
    5 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    13 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    19 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    24 to 32 inches: slow (0.06 to 0.2 inches/hour)
    32 to 72 inches: slow (0.06 to 0.2 inches/hour)

Use and Management

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations due to moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.

- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- The depth to bedrock and hardness of the bedrock in some areas greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock in some areas reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.

- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- Depth to hard bedrock in some areas may limit site preparation such as shaping and grading and restrict installation of roads and streets.

931D—Mundalite-Rawsonville complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep to moderately deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland (fig. 14). Areas range from 10 to 1,530 acres in size.

Map Unit Composition

Major Components
Mundalite, rocky, very bouldery: 45 percent
Rawsonville, rocky, very bouldery: 30 percent

Inclusions
Hogback: 6 percent
Knob Lock: 6 percent
Becket: 5 percent
Ampersand: 4 percent
Unnamed: 3 percent
Rock outcrop: 1 percent

The Hogback, Knob Lock, Becket, and somewhat poorly drained Ampersand soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Hogback, Knob Lock, and Becket soils occupy similar positions, but

Hogback soils are shallow to bedrock; Knob Lock soils are organic and shallow to very shallow to bedrock; and Becket soils have lower organic matter content. Ampersand soils occupy lower positions and are on drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
Mundalite, rocky, very bouldery: no
Rawsonville, rocky, very bouldery: no

Hydrologic group:
- Mundalite, rocky, very bouldery: C
- Rawsonville, rocky, very bouldery: B

Soil Properties and Qualities

Mundalite, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 25 to 40 inches to densic material
Depth to seasonal high water table: 25 to 40 inches
- Water table kind: perched

Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)

Figure 14.—Oblique aerial view of Boreas Ponds in the town of North Hudson. The facing ridge illustrates typical soil patterns of glaciated hillsides and ridges in the county at elevations above 2,000 feet. The very deep Mundalite and moderately deep Rawsonville soils occupy generally the lower one half of the slope, where nearly pure stands of northern hardwoods (light brown areas) predominant. The upper half of this ridge is first occupied by moderately deep Rawsonville and shallow Hogback soils up to 3,000 feet in elevation, where mixed stands of hardwoods and conifers predominant. Above 3,000 feet in elevation, steep to very steep landforms are occupied by moderately deep Santanoni and Wallface, and shallow to very shallow Skylight, Couchsachraga, and Ricker soils, where nearly pure stands of Spruce and Fir predominate.

3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)

Permeability:
0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 to 37 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
37 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Rawsonville, rocky, very bouldery

Drainage class: well drained

25 inches, bedrock

Use and Management

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. - 20 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 25 inches, bedrock

Use and Management

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness. Consult the Water Features table for months of seasonal saturation.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.

932C—Mundalite-Ampersand complex, 0 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, nearly level to strongly sloping, and well drained or somewhat poorly drained. It is on backslopes and shoulders of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 25 to 1,705 acres in size.

Map Unit Composition

Major Components
Mundalite, very bouldery: 45 percent
Ampersand, very bouldery: 30 percent

Inclusions
Wilmington: 9 percent
Rawsonville: 6 percent
Becket: 5 percent
Adirondack: 2 percent
Monadnock: 2 percent
Unnamed: 1 percent

The poorly drained Wilmington, Rawsonville, Becket, Adirondack, and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Rawsonville, Becket, and Monadnock soils occupy similar positions as Mundalite soils, but Rawsonville soils are moderately deep to bedrock; Becket and Monadnock soils have lower organic matter content; and Monadnock soils lack a dense substratum. Adirondack soils occupy similar positions as Ampersand soils, but have lower organic matter content. Wilmington soils are on depressions and drainageways. Included areas can occupy about 25 percent of this unit.

Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
  3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
  5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
  14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
  27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
  37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)

Permeability:
0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 to 37 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
37 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Ampersand, very bouldery
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 40 inches to densic material
Depth to seasonal high water table: 6 to 18 inches
Water table kind: perched
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
3 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
5 to 13 inches: extremely acid to strongly acid (3.5 to 5.5)
13 to 19 inches: extremely acid to strongly acid (3.5 to 5.5)
19 to 24 inches: very strongly acid to moderately acid (4.5 to 6.0)
24 to 32 inches: very strongly acid to moderately acid (4.5 to 6.0)
32 to 72 inches: very strongly acid to moderately acid (4.5 to 6.0)
Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)

13 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
19 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
24 to 32 inches: slow (0.06 to 0.2 inches/hour)
32 to 72 inches: slow (0.06 to 0.2 inches/hour)

Use and Management

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse

grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

932D—Mundalite-Ampersand complex, 15 to 35 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, moderately steep and steep, and well drained or somewhat poorly drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 30 to 1,110 acres in size.

Map Unit Composition

Major Components

Mundalite, very bouldery: 45 percent
Ampersand, very bouldery: 30 percent

Inclusions

Rawsonville: 9 percent
Wilmington: 6 percent
Becket: 5 percent
Adirondack: 2 percent
Monadnock: 2 percent
Unnamed: 1 percent

The Rawsonville, poorly drained Wilmington, Becket, Adirondack, and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Rawsonville, Becket, and Monadnock soils occupy similar positions as Mundalite soils, but Rawsonville soils are moderately deep to bedrock; Becket and Monadnock soils have lower organic matter content; and Monadnock soils lack a dense substratum. Adirondack soils occupy similar positions as Ampersand soils but have lower organic matter content. Wilmington soils are on drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Mundalite, very bouldery: no
  Ampersand, very bouldery: no
Hydrologic group:
  Mundalite, very bouldery: C
  Ampersand, very bouldery: B/D

Soil Properties and Qualities

Mundalite, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 25 to 40 inches to densic material
Depth to seasonal high water table: 25 to 40 inches
Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)

4 to 5 inches: moderate to rapid (0.6 to 20 inches/hour)
5 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
19 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
24 to 32 inches: slow (0.06 to 0.2 inches/hour)
32 to 72 inches: slow (0.06 to 0.2 inches/hour)

Use and Management

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

934C—Ampersand-Wilmington complex, 0 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, nearly level to strongly sloping, and somewhat poorly drained or poorly drained. It is on toeslopes and footslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 15 to 960 acres in size.

Map Unit Composition

Major Components
Ampersand, very bouldery: 45 percent
Wilmington, very bouldery: 30 percent

Inclusions
Burnt Vly: 9 percent
Adirondack: 6 percent
Tahawus: 4 percent
Rawsonville: 3 percent
Mundalite: 2 percent
Unnamed: 1 percent

The very poorly drained Burnt Vly and Tahawus, Adirondack, and well drained Rawsonville and Mundalite soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Burnt Vly and Tahawus soils occupy similar positions as Wilmington soils, but Burnt Vly soils are organic and Tahawus soils are sandy. Adirondack soils occupy similar positions as Ampersand soils but have less organic matter. Rawsonville and Mundalite soils occupy higher positions, and Rawsonville soils are moderately deep to bedrock. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

19 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Areas of poorly drained and very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.

- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

941C—Rawsonville-Hogback complex, 3 to 15 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, moderately deep to shallow, gently sloping to strongly sloping, and well drained. It is on summits, shoulders, and backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 15 to 240 acres in size.

Map Unit Composition

Major Components
Rawsonville, very rocky, very bouldery: 45 percent
Hogback, very rocky, very bouldery: 30 percent

Inclusions
Ampersand: 5 percent
Knob Lock: 5 percent
Mundalite: 5 percent
Rock outcrop: 4 percent
Lyman: 2 percent
Tunbridge: 2 percent
Unnamed: 2 percent

The somewhat poorly drained Ampersand, Knob Lock, Mundalite, Lyman, and Tunbridge soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Knob Lock, Mundalite, Lyman, and Tunbridge soils occupy similar positions, but Knob Lock soils are organic; Mundalite soils are very deep; and Lyman and Tunbridge soils have less organic matter. Ampersand soils are on small depressions and drainageways, and are very deep to bedrock. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

4 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
6 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 inches, bedrock

Use and Management

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep and shallow soils.
- Employing larger, more powerful machinery during construction and locating haul

roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

941D—Rawsonville-Hogback complex, 15 to 35 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, moderately deep to shallow, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 10 to 940 acres in size.

Map Unit Composition

Major Components
Rawsonville, very rocky, very bouldery: 45 percent
Hogback, very rocky, very bouldery: 30 percent

Inclusions
Knob Lock: 5 percent
Mundalite: 5 percent
Rock outcrop: 5 percent
Ampersand: 4 percent
Lyman: 2 percent
Tunbridge: 2 percent
Unnamed: 2 percent

The Knob Lock, Mundalite, somewhat poorly drained Ampersand, Lyman, and Tunbridge soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Knob Lock, Mundalite, Lyman, and Tunbridge soils occupy similar positions, but Knob Lock soils are organic; Mundalite soils are very deep, and Lyman and Tunbridge soils have less organic matter. Ampersand soils are on drainageways, and are very deep to bedrock. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Rawsonville, very rocky, very bouldery: no

6 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 inches, bedrock

Use and Management

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and re-seeding bare surfaces will help overcome construction and maintenance limitations of haul roads due to steep slopes.

- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations due to moderately deep and shallow soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations due to very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

Use and Management

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by moderately deep and shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.

- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding

skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

948F—Rock outcrop-Knob Lock-Hogback complex, 35 to 60 percent slopes, very bouldery

Setting

This broadly defined map unit consists of areas of exposed bedrock and soils that are loamy and organic, shallow to very shallow, very steep, and well drained to excessively drained. It is on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 20 to 200 acres in size.

Map Unit Composition

Major Components
Rock outcrop, very bouldery: 40 percent
Knob Lock, very bouldery: 30 percent
Hogback, very bouldery: 20 percent

Inclusions
Rawsonville: 5 percent
Lyman: 3 percent
Unnamed: 2 percent

The Rawsonville and Lyman soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Rawsonville and Lyman soils occupy similar positions, but Rawsonville soils are moderately deep to bedrock, and Lyman soils have less organic matter. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
- Rock outcrop, very bouldery: unranked
- Knob Lock, very bouldery: no
- Hogback, very bouldery: no

Hydrologic group:
- Rock outcrop, very bouldery: unranked
- Knob Lock, very bouldery: D
- Hogback, very bouldery: D

Rock outcrop, very bouldery
Characteristics not defined for this component.

Knob Lock, very bouldery
Drainage class: well drained
Depth to bedrock: 1 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: non-saturated organic material over loamy till derived from gneiss
Reaction (pH):
- 0 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
- 3 to 7 inches: ultra acid or extremely acid (1.8 to 4.4)
- 7 to 9 inches: extremely acid or very strongly acid (3.5 to 5.0)
- 9 inches, bedrock

Permeability:
- 0 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 3 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 9 inches: moderate to very rapid (0.6 to 100 inches/hour)
- 9 inches, bedrock

Hogback, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 10 to 20 inches

Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
3 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
4 to 6 inches: extremely acid to strongly acid (3.5 to 5.5)
6 to 14 inches: extremely acid to strongly acid (3.5 to 5.5)
14 inches, bedrock
Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
6 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 inches, bedrock

Use and Management

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

971D—Esther-Wallface complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep to moderately deep, moderately steep and steep, and moderately well drained to well drained. It is on backslopes of glaciated mountain slopes in the Adirondack High Peaks Region. Areas range from 25 to 620 acres in size.

Map Unit Composition

Major Components
Esther, rocky, very bouldery: 45 percent
Wallface, rocky, very bouldery: 30 percent

Inclusions
Andic Cryaquods: 9 percent
Unnamed: 6 percent
Santanoni: 4 percent
Skylight: 3 percent
Ricker: 2 percent
Rock outcrop: 1 percent

The somewhat poorly drained Andic Cryaquods, somewhat excessively drained and excessively drained Santanoni and Skylight, and Ricker soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Santanoni, Skylight, and Ricker soils occupy similar positions, but Santanoni soils are sandy and gravelly; Skylight soils are shallow to bedrock and are sandy; and Ricker soils are organic and shallow to very shallow to bedrock. Andic Cryaquods soils are on drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Esther, rocky, very bouldery: no
  Wallface, rocky, very bouldery: no
Hydrologic group:
  Esther, rocky, very bouldery: B
  Wallface, rocky, very bouldery: B

Soil Properties and Qualities

Esther, rocky, very bouldery
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 39 inches to densic material
Depth to seasonal high water table: 24 to 36 inches
  Water table kind: perched
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated mountain slopes
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
  4 to 8 inches: ultra acid or extremely acid (1.8 to 4.4)
  8 to 10 inches: ultra acid to very strongly acid (1.8 to 5.0)
  10 to 22 inches: extremely acid to strongly acid (3.5 to 5.5)
  22 to 28 inches: extremely acid to strongly acid (3.5 to 5.5)
  28 to 33 inches: extremely acid to strongly acid (3.5 to 5.5)
  33 to 72 inches: extremely acid to strongly acid (3.5 to 5.5)
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 4 inches: moderately rapid or rapid (2 to 20 inches/hour)
  4 to 8 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  8 to 10 inches: moderate to rapid (0.6 to 20 inches/hour)
  10 to 22 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  22 to 28 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  28 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  33 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Wallface, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 20 to 40 inches

Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated mountain slopes
Parent material: loamy till derived from gneiss
Reaction (pH):
    0 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
    4 to 9 inches: ultra acid or extremely acid (1.8 to 4.4)
    9 to 10 inches: ultra acid to very strongly acid (1.8 to 5.0)
    10 to 18 inches: extremely acid to strongly acid (3.5 to 5.5)
    18 to 25 inches: extremely acid to strongly acid (3.5 to 5.5)
    25 to 35 inches: extremely acid to strongly acid (3.5 to 5.5)
    35 to 38 inches: extremely acid to strongly acid (3.5 to 5.5)
    38 inches, bedrock
Permeability:
    0 to 4 inches: moderately rapid or rapid (2 to 20 inches/hour)
    4 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    9 to 10 inches: moderate to rapid (0.6 to 20 inches/hour)
    10 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    18 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    25 to 35 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    35 to 38 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    38 inches, bedrock

Use and Management

The areas of the county above 3,000 feet in elevation, within the cryic soil temperature zone, lie almost entirely within the New York State Forest Preserve. They cover approximately 76,750 acres or about 7 percent of the county. Because these areas have been designated “forever wild” by law, discussions of land use interpretations of the soils for agriculture, forestry, and residential development are not necessary, as these parts of the county are not subject to development for these uses. Interpretive data for these uses however, can still be found in the tables. The primary uses for interpretive data for these high elevation soils probably will be broad-based engineering interpretations for watershed planning, recreational uses, and environmental management of these unique ecological areas.

The majority of these soils, about 75 percent, are shallow or very shallow to bedrock, 15 percent are moderately deep to bedrock, and only 10 percent are very deep. Ricker, Couchsachraga, and Skylight soils are very shallow (1 to 10 inches over bedrock) or shallow (10 to 20 inches over bedrock). Wallface and Santanoni soils are moderately deep (20 to 40 inches over bedrock). Esther and Andic Cryaquods soils are very deep (greater than 60 inches deep to bedrock).

An example of an engineering interpretation for these soils would entail estimating the water storage capacity of the watershed for planning purposes downstream, such as sizing of road culverts and construction or rehab of bridges. Shallow soils would have the least storage capability within the watershed. However, water holding capacity of these soils is greatly increased, compared to other soils in the county of the same depth class, because of their very high content of organic matter and amorphous materials (complexes of iron and aluminum oxides).

Interpretations for recreational uses in the High Peaks Region center on impacts to soil resources from hiking and camping. Because of the very high organic matter

and amorphous material content in the subsoil, these high elevation soils have low bearing strength, especially when wet. Special care should be taken when locating and constructing trails and campsites to avoid compaction and subsequent erosion. Trail design needs to address the unstable nature of these soils, especially those that are shallow to bedrock. Switchbacks should be employed in trail design and grades should not exceed 10 percent. Long grades should employ diversions to slow water velocity during peak runoff events and reduce trail erosion. Cribbing structures should be utilized to stabilize shallow soils.

These high elevation soils are truly unique ecologically. The surfaces of some of these soils have an organic layer that can exceed 20 inches thick on an otherwise well-drained landform. These organic deposits build up because of cold temperatures and acidic soil conditions which lead to low microbial activity and low oxidation rates of the organic matter. The subsoils are also very high in organic matter and in many cases are at the break between mineral and organic soil material. Subsoils are also highly acidic, some with pH's less than 3.5 (ultra acid), and have very high contents of oxides of iron and aluminum (amorphous materials). Amorphous materials are mineral assemblages rich in iron and aluminum with very high water holding capacity and reactivity similar to clays, but lack the structure and plasticity. These soils, although not very extensive, may be a very important medium for carbon sequestration.

975C—Andic Cryaquods-Esther complex, 3 to 15 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, gently to strongly sloping, and somewhat poorly drained to moderately well drained. It is on footslopes and backslopes of glaciated mountain slopes in the Adirondack High Peaks Region (fig. 15). Areas range from 20 to 110 acres in size.

Map Unit Composition

Major Components
Andic Cryaquods, very bouldery: 45 percent
Esther, very bouldery: 35 percent

Inclusions
Unnamed: 10 percent
Wallface: 5 percent
Santanoni: 3 percent
Skylight: 2 percent

The Wallface and the somewhat excessively drained and excessively drained Santanoni and Skylight soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Wallface, Santanoni, and Skylight soils occupy similar positions as Esther soils, but Wallface and Santanoni soils are moderately deep to bedrock, Santanoni soils are sandy and gravelly, and Skylight soils are shallow to bedrock and are sandy. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
Andic Cryaquods, very bouldery: no
Esther, very bouldery: no

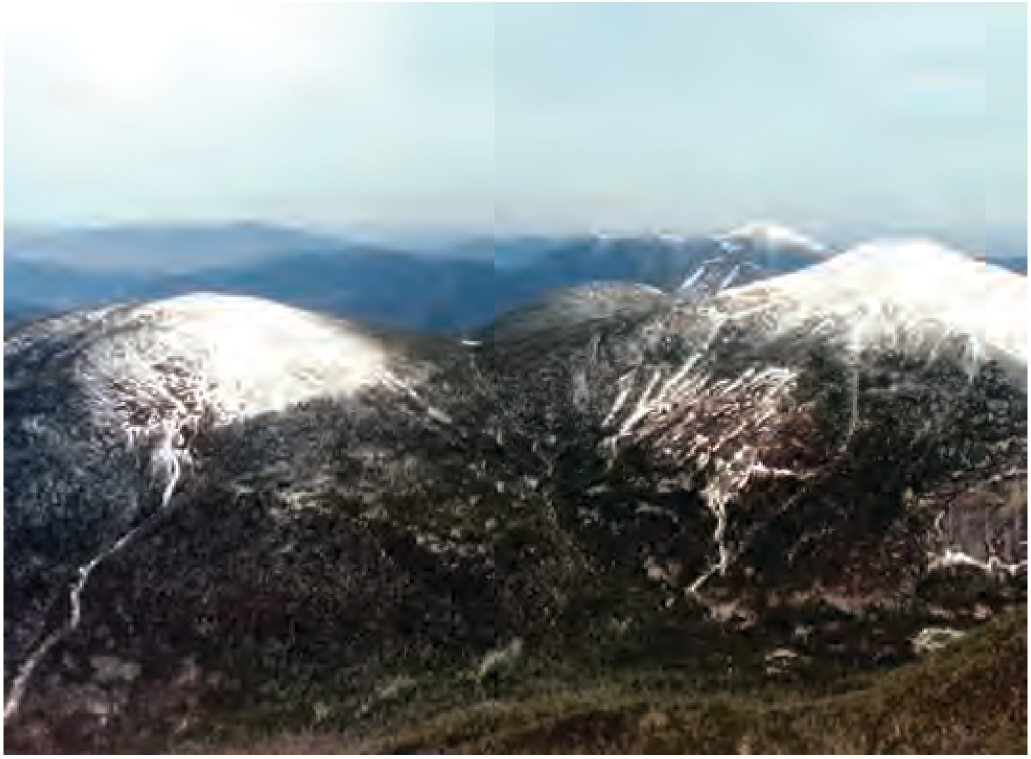

Figure 15.—Oblique aerial view of Mount Marcy (right) and Mount Skylight (left), with Panther Gorge in the lower foreground, in the town of Keene looking northwest. This view illustrates typical soil patterns of glaciated mountainsides in the High Peaks Region at elevations above 3,000 feet. One of the few occurrences of very deep soil areas above 3,000 feet in elevation is found in the bottom of Panther Gorge, which is occupied by the Andic Cryaquods-Esther complexes. As one moves up the slope, soil depth thins rapidly. The moderately deep to shallow Wallface-Skylight and Santanoni-Skylight complexes generally occupy the relatively deeper hollow (concave) areas. The shallow to very shallow Ricker-Couchsachraga-Skylight complexes occupy the forested nose (convex) slope areas. The open alpine areas and the very steep exposed landslide areas are occupied by the Rock Outcrop-Ricker-Skylight complex.

Hydrologic group:
- Andic Cryaquods, very bouldery: B/D
- Esther, very bouldery: B

Soil Properties and Qualities

Andic Cryaquods, very bouldery

Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 39 inches to densic material
Depth to seasonal high water table: 12 to 24 inches
- Water table kind: perched

Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated mountain slopes

Use and Management

The areas of the county above 3,000 feet in elevation, within the cryic soil temperature zone, lie almost entirely within the New York State Forest Preserve. They cover approximately 76,750 acres or about 7 percent of the county. Because these areas have been designated “forever wild” by law, discussions of land use interpretations of the soils for agriculture, forestry, and residential development are not necessary, as these parts of the county are not subject to development for these

uses. Interpretive data for these uses however, can still be found in the tables. The primary uses for interpretive data for these high elevation soils probably will be broad-based engineering interpretations for watershed planning, recreational uses, and environmental management of these unique ecological areas.

The majority of these soils, about 75 percent, are shallow or very shallow to bedrock, 15 percent are moderately deep to bedrock, and only 10 percent are very deep. Ricker, Couchsachraga, and Skylight soils are very shallow (1 to 10 inches over bedrock) or shallow (10 to 20 inches over bedrock). Wallface and Santanoni soils are moderately deep (20 to 40 inches over bedrock). Esther and Andic Cryaquods soils are very deep (greater than 60 inches deep to bedrock).

An example of an engineering interpretation for these soils would entail estimating the water storage capacity of the watershed for planning purposes downstream, such as sizing of road culverts and construction or rehab of bridges. Shallow soils would have the least storage capability within the watershed. However, water holding capacity of these soils is greatly increased, compared to other soils in the county of the same depth class, because of their very high content of organic matter and amorphous materials (complexes of iron and aluminum oxides).

Interpretations for recreational uses in the High Peaks Region center on impacts to soil resources from hiking and camping. Because of the very high organic matter and amorphous material content in the subsoil, these high elevation soils have low bearing strength, especially when wet. Special care should be taken when locating and constructing trails and campsites to avoid compaction and subsequent erosion. Trail design needs to address the unstable nature of these soils, especially those that are shallow to bedrock. Switchbacks should be employed in trail design and grades should not exceed 10 percent. Long grades should employ diversions to slow water velocity during peak runoff events and reduce trail erosion. Cribbing structures should be utilized to stabilize shallow soils.

These high elevation soils are truly unique ecologically. The surfaces of some of these soils have an organic layer that can exceed 20 inches thick on an otherwise well-drained landform. These organic deposits build up because of cold temperatures and acidic soil conditions which lead to low microbial activity and low oxidation rates of the organic matter. The subsoils are also very high in organic matter and in many cases are at the break between mineral and organic soil material. Subsoils are also highly acidic, some with pH’s less than 3.5 (ultra acid), and have very high contents of oxides of iron and aluminum (amorphous materials). Amorphous materials are mineral assemblages rich in iron and aluminum with very high water holding capacity and reactivity similar to clays, but lack the structure and plasticity. These soils, although not very extensive, may be a very important medium for carbon sequestration.

975D—Esther-Andic Cryaquods complex, 15 to 35 percent slopes, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy, very deep, moderately steep and steep, and moderately well drained to somewhat poorly drained. It is on backslopes of glaciated mountain slopes in the Adirondack High Peaks Region. Areas range from 70 to 230 acres in size.

Map Unit Composition

Major Components
Esther, very bouldery: 45 percent
Andic Cryaquods, very bouldery: 35 percent

Inclusions
Unnamed: 10 percent
Wallface: 5 percent
Santanoni: 3 percent
Skylight: 2 percent

The Wallface and the somewhat excessively drained and excessively drained Santanoni and Skylight soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Wallface, Santanoni, and Skylight soils occupy similar positions as Esther soils, but Wallface and Santanoni soils are moderately deep to bedrock; Santanoni soils are sandy and gravelly; and Skylight soils are shallow to bedrock and are sandy. Included areas can occupy about 25 percent of this unit.

Permeability:
0 to 7 inches: moderately rapid or rapid (2 to 20 inches/hour)
7 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
11 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
24 to 36 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
36 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

The areas of the county above 3,000 feet in elevation, within the cryic soil temperature zone, lie almost entirely within the New York State Forest Preserve. They cover approximately 76,750 acres or about 7 percent of the county. Because these areas have been designated “forever wild” by law, discussions of land use interpretations of the soils for agriculture, forestry, and residential development are not necessary, as these parts of the county are not subject to development for these uses. Interpretive data for these uses however, can still be found in the tables. The primary uses for interpretive data for these high elevation soils probably will be broad-based engineering interpretations for watershed planning, recreational uses, and environmental management of these unique ecological areas.

The majority of these soils, about 75 percent, are shallow or very shallow to bedrock, 15 percent are moderately deep to bedrock, and only 10 percent are very deep. Ricker, Couchsachraga, and Skylight soils are very shallow (1 to 10 inches over bedrock) or shallow (10 to 20 inches over bedrock). Wallface and Santanoni soils are moderately deep (20 to 40 inches over bedrock). Esther and Andic Cryaquods soils are very deep (greater than 60 inches deep to bedrock).

An example of an engineering interpretation for these soils would entail estimating the water storage capacity of the watershed for planning purposes downstream, such as sizing of road culverts and construction or rehab of bridges. Shallow soils would have the least storage capability within the watershed. However, water holding capacity of these soils is greatly increased, compared to other soils in the county of the same depth class, because of their very high content of organic matter and amorphous materials (complexes of iron and aluminum oxides).

Interpretations for recreational uses in the High Peaks Region center on impacts to soil resources from hiking and camping. Because of the very high organic matter and amorphous material content in the subsoil, these high elevation soils have low bearing strength, especially when wet. Special care should be taken when locating and constructing trails and campsites to avoid compaction and subsequent erosion. Trail design needs to address the unstable nature of these soils, especially those that are shallow to bedrock. Switchbacks should be employed in trail design and grades should not exceed 10 percent. Long grades should employ diversions to slow water velocity during peak runoff events and reduce trail erosion. Cribbing structures should be utilized to stabilize shallow soils.

These high elevation soils are truly unique ecologically. The surfaces of some of these soils have an organic layer that can exceed 20 inches thick on an otherwise well-drained landform. These organic deposits build up because of cold temperatures and acidic soil conditions which lead to low microbial activity and low oxidation rates of the organic matter. The subsoils are also very high in organic matter and in many cases are at the break between mineral and organic soil material. Subsoils are also highly acidic, some with pH's less than 3.5 (ultra acid), and have very high contents of oxides of iron and aluminum (amorphous materials). Amorphous materials are mineral assemblages rich in iron and aluminum with very high water holding capacity and reactivity similar to clays, but lack the structure and plasticity. These soils, although not very extensive, may be a very important medium for carbon sequestration.

992D—Wallface-Skylight complex, 15 to 35 percent slopes, very rocky, very bouldery

Setting

This broadly defined map unit consists of soils that are loamy and sandy, moderately deep to shallow, moderately steep and steep, and well drained to somewhat excessively drained. It is on summits, shoulders, and backslopes of glaciated mountain slopes in the Adirondack High Peaks Region. Areas range from 15 to 620 acres in size.

Map Unit Composition

Major Components
Wallface, very rocky, very bouldery: 45 percent
Skylight, very rocky, very bouldery: 30 percent

Inclusions
Ricker: 10 percent
Couchsachraga: 5 percent
Esther: 4 percent
Rock outcrop: 3 percent
Santanoni: 2 percent
Unnamed: 1 percent

The Ricker, Couchsachraga, Esther, and Santanoni soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Ricker, Couchsachraga, Esther, and Santanoni soils occupy similar positions, but Ricker soils are organic; Couchsachraga soils are very shallow; Esther soils are very deep; and Santanoni soils are sandy and gravelly. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

Land capability classification: 7s

Parent material: sandy colluvium derived from gneiss and/or sandy residuum weathered from gneiss and/or sandy till derived from gneiss
Reaction (pH):
- 0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
- 2 to 5 inches: ultra acid or extremely acid (1.8 to 4.4)
- 5 to 9 inches: ultra acid to very strongly acid (1.8 to 5.0)
- 9 to 15 inches: extremely acid to strongly acid (3.5 to 5.5)
- 15 inches, bedrock

Permeability:
0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 9 inches: rapid or very rapid (6 to 100 inches/hour)
9 to 15 inches: rapid or very rapid (6 to 100 inches/hour)
15 inches, bedrock

Use and Management

The areas of the county above 3,000 feet in elevation, within the cryic soil temperature zone, lie almost entirely within the New York State Forest Preserve. They cover approximately 76,750 acres or about 7 percent of the county. Because these areas have been designated “forever wild” by law, discussions of land use interpretations of the soils for agriculture, forestry, and residential development are not necessary, as these parts of the county are not subject to development for these uses. Interpretive data for these uses however, can still be found in the tables. The primary uses for interpretive data for these high elevation soils probably will be broad-based engineering interpretations for watershed planning, recreational uses, and environmental management of these unique ecological areas.

The majority of these soils, about 75 percent, are shallow or very shallow to bedrock, 15 percent are moderately deep to bedrock, and only 10 percent are very

deep. Ricker, Couchsachraga, and Skylight soils are very shallow (1 to 10 inches over bedrock) or shallow (10 to 20 inches over bedrock). Wallface and Santanoni soils are moderately deep (20 to 40 inches over bedrock). Esther and Andic Cryaquods soils are very deep (greater than 60 inches deep to bedrock).

An example of an engineering interpretation for these soils would entail estimating the water storage capacity of the watershed for planning purposes downstream, such as sizing of road culverts and construction or rehab of bridges. Shallow soils would have the least storage capability within the watershed. However, water holding capacity of these soils is greatly increased, compared to other soils in the county of the same depth class, because of their very high content of organic matter and amorphous materials (complexes of iron and aluminum oxides).

Interpretations for recreational uses in the High Peaks Region center on impacts to soil resources from hiking and camping. Because of the very high organic matter and amorphous material content in the subsoil, these high elevation soils have low bearing strength, especially when wet. Special care should be taken when locating and constructing trails and campsites to avoid compaction and subsequent erosion. Trail design needs to address the unstable nature of these soils, especially those that are shallow to bedrock. Switchbacks should be employed in trail design and grades should not exceed 10 percent. Long grades should employ diversions to slow water velocity during peak runoff events and reduce trail erosion. Cribbing structures should be utilized to stabilize shallow soils.

These high elevation soils are truly unique ecologically. The surfaces of some of these soils have an organic layer that can exceed 20 inches thick on an otherwise well-drained landform. These organic deposits build up because of cold temperatures and acidic soil conditions which lead to low microbial activity and low oxidation rates of the organic matter. The subsoils are also very high in organic matter and in many cases are at the break between mineral and organic soil material. Subsoils are also highly acidic, some with pH's less than 3.5 (ultra acid), and have very high contents of oxides of iron and aluminum (amorphous materials). Amorphous materials are mineral assemblages rich in iron and aluminum with very high water holding capacity and reactivity similar to clays, but lack the structure and plasticity. These soils, although not very extensive, may be a very important medium for carbon sequestration.

998F—Rock outcrop-Ricker-Skylight complex, 35 to 80 percent slopes, very bouldery

Setting

This broadly defined map unit consists of areas of exposed bedrock and soils that are organic and sandy, shallow to very shallow, very steep, and well drained to excessively drained. It is on backslopes of glaciated mountain slopes in the Adirondack High Peaks Region. Areas range from 15 to 585 acres in size.

Map Unit Composition

Major Components
Rock outcrop, very bouldery: 30 percent
Ricker, very bouldery: 25 percent
Skylight, very bouldery: 20 percent

Inclusions
Couchsachraga: 10 percent
Santanoni: 5 percent
Unnamed: 5 percent
Wallface: 3 percent
Esther: 2 percent

The Couchsachraga, Santanoni, Wallface, and Esther soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Couchsachraga, Santanoni, Wallface, and Esther soils occupy similar positions, but Santanoni soils are moderately deep, Wallface soils are moderately deep and are loamy, and Esther soils are very deep and loamy. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
    Rock outcrop, very bouldery: unranked
    Ricker, very bouldery: no
    Skylight, very bouldery: no
Hydrologic group:
    Rock outcrop, very bouldery: unranked
    Ricker, very bouldery: D
    Skylight, very bouldery: D

Rock outcrop, very bouldery
Characteristics not defined for this component.

Ricker, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 1 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate to low
Potential frost action: low
Shrink-swell potential: not rated
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated mountain slopes
Parent material: non-saturated organic material
Reaction (pH):
    0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
    1 to 6 inches: ultra acid or extremely acid (1.8 to 4.4)
    6 to 11 inches: ultra acid or extremely acid (1.8 to 4.4)
    11 inches, bedrock
Permeability:
    0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
    1 to 6 inches: moderately rapid or rapid (2 to 20 inches/hour)
    6 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    11 inches, bedrock

Skylight, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate to low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery

Landform: glaciated mountain slopes
Parent material: sandy colluvium derived from gneiss and/or sandy residuum weathered from gneiss and/or sandy till derived from gneiss
Reaction (pH):
0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 5 inches: ultra acid or extremely acid (1.8 to 4.4)
5 to 9 inches: ultra acid to very strongly acid (1.8 to 5.0)
9 to 15 inches: extremely acid to strongly acid (3.5 to 5.5)
15 inches, bedrock
Permeability:
0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 9 inches: rapid or very rapid (6 to 100 inches/hour)
9 to 15 inches: rapid or very rapid (6 to 100 inches/hour)
15 inches, bedrock

Use and Management

The areas of the county above 3,000 feet in elevation, within the cryic soil temperature zone, lie almost entirely within the New York State Forest Preserve. They cover approximately 76,750 acres or about 7 percent of the county. Because these areas have been designated “forever wild” by law, discussions of land use interpretations of the soils for agriculture, forestry, and residential development are not necessary, as these parts of the county are not subject to development for these uses. Interpretive data for these uses however, can still be found in the tables. The primary uses for interpretive data for these high elevation soils probably will be broad-based engineering interpretations for watershed planning, recreational uses, and environmental management of these unique ecological areas.

The majority of these soils, about 75 percent, are shallow or very shallow to bedrock, 15 percent are moderately deep to bedrock, and only 10 percent are very deep. Ricker, Couchsachraga, and Skylight soils are very shallow (1 to 10 inches over bedrock) or shallow (10 to 20 inches over bedrock). Wallface and Santanoni soils are moderately deep (20 to 40 inches over bedrock). Esther and Andic Cryaquods soils are very deep (greater than 60 inches deep to bedrock).

An example of an engineering interpretation for these soils would entail estimating the water storage capacity of the watershed for planning purposes downstream, such as sizing of road culverts and construction or rehab of bridges. Shallow soils would have the least storage capability within the watershed. However, water holding capacity of these soils is greatly increased, compared to other soils in the county of the same depth class, because of their very high content of organic matter and amorphous materials (complexes of iron and aluminum oxides).

Interpretations for recreational uses in the High Peaks Region center on impacts to soil resources from hiking and camping. Because of the very high organic matter and amorphous material content in the subsoil, these high elevation soils have low bearing strength, especially when wet. Special care should be taken when locating and constructing trails and campsites to avoid compaction and subsequent erosion. Trail design needs to address the unstable nature of these soils, especially those that are shallow to bedrock. Switchbacks should be employed in trail design and grades should not exceed 10 percent. Long grades should employ diversions to slow water velocity during peak runoff events and reduce trail erosion. Cribbing structures should be utilized to stabilize shallow soils.

These high elevation soils are truly unique ecologically. The surfaces of some of these soils have an organic layer that can exceed 20 inches thick on an otherwise well-drained landform. These organic deposits build up because of cold temperatures

and acidic soil conditions which lead to low microbial activity and low oxidation rates of the organic matter. The subsoils are also very high in organic matter and in many cases are at the break between mineral and organic soil material. Subsoils are also highly acidic, some with pH's less than 3.5 (ultra acid), and have very high contents of oxides of iron and aluminum (amorphous materials). Amorphous materials are mineral assemblages rich in iron and aluminum with very high water holding capacity and reactivity similar to clays, but lack the structure and plasticity. These soils, although not very extensive, may be a very important medium for carbon sequestration.

AdA—Adams loamy sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and somewhat excessively drained. It is on summits of deltas, outwash plains, and kame terraces in the Adirondack Upland. Areas range from 5 to 350 acres in size.

Map Unit Composition

Major Components
Adams: 85 percent

Inclusions
Colton: 5 percent
Duxbury: 5 percent
Croghan: 4 percent
Unnamed: 1 percent

The excessively drained Colton, well drained Duxbury, and moderately well drained Croghan soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton and Duxbury soils occupy similar positions, but Colton soils are sandy and gravelly, and Duxbury soils are loamy over sandy or gravelly. Croghan soils are on small depressions or drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3s
Hydric soil rating:
  Adams: no
Hydrologic group:
  Adams: A

Soil Properties and Qualities

Adams
Drainage class: somewhat excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: deltas, kame terraces, outwash plains
Parent material: sandy glaciolacustrine deposits derived from gneiss

Reaction (pH):
0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
4 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
5 to 8 inches: very strongly acid to moderately acid (4.5 to 6.0)
8 to 14 inches: very strongly acid to moderately acid (4.5 to 6.0)
14 to 23 inches: very strongly acid to moderately acid (4.5 to 6.0)
23 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
5 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Applying gravel base material during construction of haul roads will help overcome limitations due to sandy surface layers.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

AdB—Adams loamy sand, 3 to 8 percent slopes

Setting

This soil is sandy, very deep, gently sloping, and somewhat excessively drained. It is on summits and shoulders of deltas, outwash plains, and kame terraces in the Adirondack Upland. Areas range from 3 to 250 acres in size.

Map Unit Composition

Major Components
Adams: 85 percent

Inclusions
Colton: 5 percent
Duxbury: 5 percent
Croghan: 4 percent
Unnamed: 1 percent

The excessively drained Colton, well drained Duxbury, and moderately well drained Croghan soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton and Duxbury soils occupy similar positions, but Colton soils are sandy and gravelly, and Duxbury soils are loamy over sandy or gravelly. Croghan soils are in small depressions or along drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3s
Hydric soil rating:
  Adams: no

  4 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
  5 to 8 inches: very strongly acid to moderately acid (4.5 to 6.0)
  8 to 14 inches: very strongly acid to moderately acid (4.5 to 6.0)
  14 to 23 inches: very strongly acid to moderately acid (4.5 to 6.0)
  23 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)

2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
5 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

AdC—Adams loamy sand, 8 to 15 percent slopes

Setting

This soil is sandy, very deep, strongly sloping, and somewhat excessively drained.

It is on shoulders and backslopes of deltas, outwash plains, and kame terraces in the Adirondack Upland. Areas range from 4 to 210 acres in size.

Map Unit Composition

Major Components
Adams: 85 percent

Inclusions
Colton: 5 percent
Duxbury: 5 percent
Unnamed: 5 percent

The excessively drained Colton, and well drained Duxbury soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton and Duxbury soils occupy similar positions, but Colton soils are sandy and gravelly, and Duxbury soils are loamy over sandy or gravelly. Included areas can occupy about 15 percent of this unit.

  14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Applying gravel base material during construction of haul roads will help overcome limitations due to sandy surface layers.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability due to strongly sloping areas.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

AdD—Adams loamy sand, 15 to 25 percent slopes

Setting

This soil is sandy, very deep, moderately steep, and somewhat excessively drained. It is on backslopes of deltas, outwash plains, and kame terraces in the Adirondack Upland. Areas range from 3 to 230 acres in size.

Map Unit Composition

Major Components
Adams: 85 percent

Inclusions
Colton: 5 percent
Duxbury: 4 percent
Unnamed: 4 percent
Monadnock: 2 percent

The excessively drained Colton, and well drained Duxbury and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton, Duxbury, and Monadnock soils occupy similar positions, but Colton soils are sandy and gravelly; Duxbury and Monadnock soils are loamy over sandy or gravelly; and Monadnock soils are underlain by till. Included areas can occupy about 15 percent of this unit.

  14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture

- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

  4 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
  5 to 8 inches: very strongly acid to moderately acid (4.5 to 6.0)
  8 to 14 inches: very strongly acid to moderately acid (4.5 to 6.0)
  14 to 23 inches: very strongly acid to moderately acid (4.5 to 6.0)
  23 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)

2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
5 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

AkA—Adirondack fine sandy loam, 0 to 3 percent slopes, very bouldery

Setting

This soil is loamy, very deep, nearly level, and somewhat poorly drained. It is on toeslopes and footslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 37 acres in size.

Map Unit Composition

Major Components
Adirondack, very bouldery: 85 percent

Inclusions
Tahawus: 5 percent
Skerry: 4 percent
Sunapee: 3 percent
Unnamed: 2 percent
Ampersand: 1 percent

The very poorly drained Tahawus, moderately well drained Skerry and Sunapee, and Ampersand soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Tahawus soils occupy lower positions, and are sandy. Skerry and Sunapee soils occupy slightly higher positions, but Sunapee soils lack the dense substratum. Ampersand soils occupy similar positions, but have higher organic matter content. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Adirondack, very bouldery: no
Hydrologic group:
  Adirondack, very bouldery: C/D

Soil Properties and Qualities

Adirondack, very bouldery
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 38 inches to densic material
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
  4 to 6 inches: extremely acid to strongly acid (3.5 to 5.5)
  6 to 8 inches: extremely acid to strongly acid (3.5 to 5.5)

8 to 9 inches: extremely acid to strongly acid (3.5 to 5.5)
9 to 18 inches: extremely acid to strongly acid (3.5 to 5.5)
18 to 26 inches: very strongly acid to moderately acid (4.5 to 6.0)
26 to 34 inches: strongly acid or moderately acid (5.1 to 6.0)
34 to 43 inches: strongly acid or moderately acid (5.1 to 6.0)
43 to 72 inches: strongly acid or moderately acid (5.1 to 6.0)

Permeability:
0 to 2 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
2 to 4 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
4 to 6 inches: moderate (0.6 to 2 inches/hour)
6 to 8 inches: moderate (0.6 to 2 inches/hour)
8 to 9 inches: moderate (0.6 to 2 inches/hour)
9 to 18 inches: moderate (0.6 to 2 inches/hour)
18 to 26 inches: moderate (0.6 to 2 inches/hour)
26 to 34 inches: slow (0.06 to 0.2 inches/hour)
34 to 43 inches: slow (0.06 to 0.2 inches/hour)
43 to 72 inches: slow (0.06 to 0.2 inches/hour)

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture

- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Planting adapted species can minimize the root damage caused by frost action.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to

them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table “Trees to Manage” section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

AkB—Adirondack fine sandy loam, 3 to 8 percent slopes, very bouldery

Setting

This soil is loamy, very deep, gently sloping, and somewhat poorly drained. It is on footslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 195 acres in size.

Map Unit Composition

Major Components
Adirondack, very bouldery: 85 percent

Inclusions
Tahawus: 5 percent
Skerry: 4 percent
Sunapee: 3 percent
Unnamed: 2 percent

The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

AmB—Amenia fine sandy loam, 2 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on summits, shoulders, and backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 365 acres in size.

Map Unit Composition

Major Components
Amenia: 85 percent

Inclusions
Nellis: 5 percent
Massena: 4 percent
Bombay: 2 percent
Cayuga: 2 percent
Unnamed: 2 percent

The well drained Nellis; somewhat poorly drained Massena, Bombay, and Cayuga soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Nellis soils occupy higher positions. Massena soils are on small depressions and drainageways. Bombay and Cayuga soils occupy similar positions, but Bombay soils have a slightly higher clay content in the subsoil, and Cayuga soils are clayey over loamy. Included areas make up about 15 percent of this unit.

  36 to 48 inches: slow (0.06 to 0.2 inches/hour)
  48 to 72 inches: slow (0.06 to 0.2 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

Pasture
- These soils are well suited to pasture.

- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

AmC—Amenia fine sandy loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and moderately well drained. It is on shoulders and backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 65 acres in size.

Map Unit Composition

Major Components
Amenia: 85 percent

Inclusions
Nellis: 6 percent
Massena: 3 percent
Bombay: 2 percent
Cayuga: 2 percent
Unnamed: 2 percent

The well drained Nellis; somewhat poorly drained Massena, Bombay, and Cayuga soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Nellis soils occupy higher positions. Massena soils are on small depressions and drainageways. Bombay and Cayuga soils occupy similar positions, but Bombay soils have a slightly higher clay content in the subsoil, and Cayuga soils are clayey over loamy. Included areas make up about 15 percent of this unit.

- 36 to 48 inches: slow (0.06 to 0.2 inches/hour)
- 48 to 72 inches: slow (0.06 to 0.2 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when

excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

BcB—Becket fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and well drained. It is on summits and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 4 to 205 acres in size.

Map Unit Composition

Major Components
Becket: 85 percent

Inclusions
Skerry: 8 percent
Adirondack: 3 percent
Monadnock: 3 percent
Unnamed: 1 percent

The moderately well drained Skerry, somewhat poorly drained Adirondack, and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Skerry soils occupy slightly lower positions. Adirondack soils are on small depressions and drainageways. Monadnock soils occupy similar positions but lack the dense substratum. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

  3 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 18 inches: extremely acid to slightly acid (3.5 to 6.5)
  18 to 33 inches: extremely acid to slightly acid (3.5 to 6.5)
  33 to 47 inches: very strongly acid to neutral (4.5 to 7.3)
  47 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
  47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

BcC—Becket fine sandy loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on backslopes and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 105 acres in size.

Map Unit Composition

Major Components
Becket: 85 percent

Inclusions
Monadnock: 5 percent

Skerry: 5 percent
Adirondack: 2 percent
Unnamed: 2 percent
Tunbridge: 1 percent

The Monadnock and Tunbridge, moderately well drained Skerry, and somewhat poorly drained Adirondack soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Monadnock and Tunbridge soils occupy similar positions but Monadnock soils lack the dense substratum, and Tunbridge soils are moderately deep to bedrock. Skerry soils occupy slightly lower positions. Adirondack soils are on small depressions and drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3e

Soil Properties and Qualities

Becket
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 36 inches to densic material
Depth to seasonal high water table: 30 to 36 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 3 inches: extremely acid to slightly acid (3.5 to 6.5)
  3 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 18 inches: extremely acid to slightly acid (3.5 to 6.5)
  18 to 33 inches: extremely acid to slightly acid (3.5 to 6.5)
  33 to 47 inches: very strongly acid to neutral (4.5 to 7.3)
  47 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
  47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

BeB—Becket fine sandy loam, 3 to 8 percent slopes, very bouldery

Setting

This soil is loamy, very deep, gently sloping, and well drained. It is on summits and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 4 to 200 acres in size.

Map Unit Composition

Major Components
Becket, very bouldery: 85 percent

Inclusions
Skerry: 8 percent
Adirondack: 3 percent
Monadnock: 3 percent
Unnamed: 1 percent

The moderately well drained Skerry, somewhat poorly drained Adirondack, and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Skerry soils occupy slightly lower positions. Adirondack soils are on small depressions and drainageways. Monadnock soils occupy similar positions but lack the dense substratum. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

- 18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
- 47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

BeC—Becket fine sandy loam, 8 to 15 percent slopes, very bouldery

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on backslopes and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 345 acres in size.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

BeD—Becket fine sandy loam, 15 to 35 percent slopes, very bouldery

Setting

This soil is loamy, very deep, steep, and well drained. It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 4 to 485 acres in size.

Map Unit Composition

Major Components
Becket, very bouldery: 85 percent

Inclusions
Monadnock: 6 percent
Unnamed: 5 percent
Tunbridge: 3 percent
Skerry: 1 percent

The Monadnock, Tunbridge, and moderately well drained Skerry soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Monadnock and Tunbridge soils occupy similar positions but Monadnock soils lack the dense substratum, and Tunbridge soils are moderately deep to bedrock. Skerry soils are on drainageways. Included areas can occupy about 15 percent of this unit.

- 5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
- 47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails

prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

BeF—Becket fine sandy loam, 35 to 60 percent slopes, very bouldery

Setting

This soil is loamy, very deep, very steep, and well drained. It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 7 to 150 acres in size.

Map Unit Composition

Major Components
Becket, very bouldery: 85 percent

Inclusions
Monadnock: 7 percent
Unnamed: 5 percent
Tunbridge: 3 percent

The Monadnock and Tunbridge soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Monadnock and Tunbridge soils occupy similar positions but Monadnock soils lack the dense substratum, and Tunbridge soils are moderately deep to bedrock. Included areas can occupy about 15 percent of this unit.

  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 18 inches: extremely acid to slightly acid (3.5 to 6.5)
  18 to 33 inches: extremely acid to slightly acid (3.5 to 6.5)
  33 to 47 inches: very strongly acid to neutral (4.5 to 7.3)
  47 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones, and the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes. Consult the Water Features table for months of seasonal saturation.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

BkC—Becket-Tunbridge complex, 8 to 15 percent slopes, rocky, very bouldery

Setting

These soils are loamy, very deep and moderately deep, strongly sloping, and well drained. They are on backslopes and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 225 acres in size.

Map Unit Composition

Major Components
Becket, rocky, very bouldery: 45 percent
Tunbridge, rocky, very bouldery: 30 percent

Inclusions
Lyman: 7 percent
Monadnock: 7 percent
Skerry: 6 percent
Adirondack: 2 percent
Unnamed: 2 percent
Rock outcrop: 1 percent

The Lyman and Monadnock, moderately well drained Skerry, and somewhat poorly drained Adirondack soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Lyman and Monadnock soils occupy similar positions but Lyman soils are shallow to bedrock, and Monadnock soils lack the dense substratum. Skerry soils occupy slightly lower positions than Becket soils. Adirondack soils are on small depressions and drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Becket, rocky, very bouldery: no
  Tunbridge, rocky, very bouldery: no
Hydrologic group:
  Becket, rocky, very bouldery: B
  Tunbridge, rocky, very bouldery: B

Soil Properties and Qualities

Becket, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 36 inches to densic material
Depth to seasonal high water table: 30 to 36 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 3 inches: extremely acid to slightly acid (3.5 to 6.5)
  3 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 18 inches: extremely acid to slightly acid (3.5 to 6.5)
  18 to 33 inches: extremely acid to slightly acid (3.5 to 6.5)
  33 to 47 inches: very strongly acid to neutral (4.5 to 7.3)
  47 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  18 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  33 to 47 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
  47 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Tunbridge, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
  3 to 4 inches: extremely acid to moderately acid (3.5 to 6.0)
  4 to 7 inches: extremely acid to moderately acid (3.5 to 6.0)
  7 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
  13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
  18 to 27 inches: strongly acid to slightly acid (5.1 to 6.5)
  27 inches, bedrock

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 4 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 27 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

BkD—Becket-Tunbridge complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

These soils are loamy, very deep and moderately deep, moderately steep and steep, and well drained. They are on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 500 acres in size.

Map Unit Composition

Major Components
Becket, rocky, very bouldery: 45 percent
Tunbridge, rocky, very bouldery: 30 percent

Inclusions
Lyman: 8 percent
Monadnock: 7 percent
Knob Lock: 5 percent
Skerry: 3 percent
Rock outcrop: 1 percent
Unnamed: 1 percent

The Lyman, Monadnock, Knob Lock, and moderately well drained Skerry soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Lyman, Monadnock, and Knob Lock soils occupy similar positions, but Lyman soils are shallow to bedrock; Monadnock soils lack the dense substratum; and Knob Lock soils are organic and very shallow to shallow. Skerry soils are on drainageways. Included areas can occupy about 15 percent of this unit.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10

percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations due to moderately deep soils.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table limits the capacity of these soils to bear a load without movement. Structures may need special design to avoid damage from wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction site development and building maintenance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.

- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

BoB—Bombay gravelly loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on summits, shoulders, and backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 5 to 95 acres in size.

Map Unit Composition

Major Components
Bombay: 85 percent

Inclusions
Nellis: 5 percent
Massena: 4 percent
Amenia: 2 percent
Cayuga: 2 percent
Unnamed: 2 percent

The well drained Nellis; somewhat poorly drained Massena, Amenia, and Cayuga soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Nellis soils occupy higher positions. Massena soils are in depressions and drainageways. Amenia and Cayuga soils occupy similar positions, but Amenia soils have lower clay content in the subsoil, and Cayuga soils are clayey over loamy. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e

Hydric soil rating:
Bombay: no
Hydrologic group:
Bombay: B/D

Soil Properties and Qualities

Bombay
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Landform: drumlinoid ridges
Parent material: not specified
Reaction (pH):
0 to 10 inches: strongly acid to slightly acid (5.1 to 6.5)
10 to 18 inches: strongly acid to neutral (5.1 to 7.3)
18 to 25 inches: strongly acid to neutral (5.1 to 7.3)
25 to 36 inches: moderately acid to slightly alkaline (5.6 to 7.8)
36 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
0 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
10 to 18 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
18 to 25 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
25 to 36 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
36 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse

grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

BuA—Bucksport mucky peat, 0 to 1 percent slopes

Setting

This soil is mucky, very deep, nearly level, and very poorly drained. It is on bogs and swamps in the Adirondack Upland. Areas range from 7 to 60 acres in size.

Map Unit Composition

Major Components
Bucksport: 85 percent

Inclusions
Wonsqueak: 5 percent
Tahawus: 3 percent

Unnamed: 3 percent
Medomak: 2 percent
Typic Endoaquolls: 2 percent

The Wonsqueak, Tahawus, Medomak, and Typic Endoaquolls soils may be included in areas of this map unit. Also included are organic soils with higher woody fragment content. Wonsqueak, Tahawus, and Typic Endoaquolls soils occupy similar positions, but Wonsqueak soils are less than 51 inches deep to mineral soil material; Tahawus soils are sandy and are on small areas underlain by till; and Typic Endoaquolls soils are loamy and are on small areas underlain by till. Medomak soils are silty and are on small flood plain areas near streams. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
  Bucksport: yes
Hydrologic group:
  Bucksport: A/D

Soil Properties and Qualities

Bucksport
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
  Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: not rated
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material
Reaction (pH):
  0 to 7 inches: extremely acid to strongly acid (3.6 to 5.5)
  7 to 31 inches: extremely acid to moderately acid (3.6 to 6.0)
  31 to 47 inches: extremely acid to moderately acid (3.6 to 6.0)
  47 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 7 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  7 to 31 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  31 to 47 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  47 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland

- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The organic matter content limits soil strength and severely affects the capacity of these soils to bear a load without movement.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields

- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets

- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.

BvA—Burnt Vly peat, 0 to 1 percent slopes

Setting

This soil is mucky, very deep, nearly level, and very poorly drained. It is on bogs and swamps in the Adirondack Upland. Areas range from 3 to 90 acres in size.

Map Unit Composition

Major Components
Burnt Vly: 85 percent

Inclusions
Pleasant Lake: 5 percent
Tahawus: 4 percent
Searsport: 3 percent
Wonsqueak: 2 percent
Rumney: 1 percent

The Pleasant Lake, Tahawus, Searsport, Wonsqueak, and poorly drained Rumney soils may be included in areas of this map unit. Pleasant Lake, Tahawus, Searsport, and Wonsqueak soils occupy similar positions, but Pleasant Lake soils are greater than 51 inches deep to mineral soil material; Searsport soils are sandy and are on small areas underlain by outwash; Tahawus soils are sandy and are on small areas underlain by till; and Wonsqueak soils have a higher pH and are mucky over loamy. Rumney soils are on small flood plain areas near streams and are loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
Burnt Vly: yes
Hydrologic group:
Burnt Vly: B/D

Soil Properties and Qualities

Burnt Vly
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material over sandy glaciofluvial deposits
Reaction (pH):
0 to 10 inches: ultra acid to very strongly acid (1.8 to 4.5)
10 to 15 inches: ultra acid to very strongly acid (1.8 to 4.5)
15 to 24 inches: ultra acid to very strongly acid (1.8 to 4.5)
24 to 34 inches: ultra acid to very strongly acid (1.8 to 4.5)
34 to 56 inches: extremely acid to slightly acid (3.5 to 6.5)
56 to 72 inches: extremely acid to slightly acid (3.5 to 6.5)
Permeability:
0 to 10 inches: moderately slow to rapid (0.2 to 20 inches/hour)
10 to 15 inches: moderately slow to rapid (0.2 to 20 inches/hour)
15 to 24 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
24 to 34 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

34 to 56 inches: moderate to very rapid (0.6 to 100 inches/hour)
56 to 72 inches: moderate to very rapid (0.6 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

• Subsidence of the organic material reduces the load-bearing capacity of these soils.

CaA—Catden muck, 0 to 1 percent slopes

Setting

This soil is mucky, very deep, nearly level, and very poorly drained. It is on marshes and swamps in the Champlain Valley. Areas range from 3 to 235 acres in size.

Map Unit Composition

Major Components
Catden: 85 percent

Inclusions
Whallonsburg: 5 percent
Livingston: 4 percent
Fluvaquents-Udifluvents: 3 percent
Unnamed: 3 percent

The Whallonsburg, Livingston, and somewhat poorly drained and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Also included are organic soils with higher woody fragment content. Whallonsburg and Livingston soils occupy similar positions, but Whallonsburg soils are less than 51 inches deep to mineral soil material, and Livingston soils are clayey. Fluvaquents-Udifluvents soils are loamy or sandy and are on small flood plain areas near streams. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w

- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The organic matter content limits soil strength and severely affects the capacity of these soils to bear a load without movement.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets

- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.

CbA—Colton very gravelly loamy sand, 0 to 3 percent slopes, very bouldery

Setting

This soil is sandy and gravelly, very deep, nearly level, and excessively drained. It is on summits of kame terraces and outwash plains in the Adirondack Upland. Areas range from 10 to 110 acres in size.

Map Unit Composition

Major Components
Colton, very bouldery: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 3 percent
Unnamed: 3 percent
Croghan: 2 percent
Monadnock: 2 percent

The somewhat excessively drained Adams, well drained Duxbury and Monadnock, and moderately well drained Croghan soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy, Duxbury and Monadnock soils are loamy over sandy or gravelly, and Monadnock soils are underlain by till. Croghan soils are in small depressions or along drainageways, and are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
    Colton, very bouldery: no
Hydrologic group:
    Colton, very bouldery: A

Soil Properties and Qualities

Colton, very bouldery
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches

Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: negligible
Surface fragment cover: very bouldery
Landform: kame terraces, outwash plains
Parent material: gravelly outwash derived from gneiss
Reaction (pH):
 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
 3 to 6 inches: extremely acid to moderately acid (3.5 to 6.0)
 6 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
 13 to 21 inches: extremely acid to moderately acid (3.5 to 6.0)
 21 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
 1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
 2 to 3 inches: rapid or very rapid (6 to 100 inches/hour)
 3 to 6 inches: rapid or very rapid (6 to 100 inches/hour)
 6 to 13 inches: rapid or very rapid (6 to 100 inches/hour)
 13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
 21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.

- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

CbB—Colton very gravelly loamy sand, 3 to 8 percent slopes, very bouldery

Setting

This soil is sandy and gravelly, very deep, gently sloping, and excessively drained. It is on summits and shoulders of kame terraces and outwash plains in the Adirondack Upland. Areas range from 5 to 140 acres in size.

Map Unit Composition

Major Components
Colton, very bouldery: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 4 percent
Unnamed: 3 percent
Monadnock: 2 percent
Croghan: 1 percent

The somewhat excessively drained Adams, well drained Duxbury and Monadnock, and moderately well drained Croghan soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy; Duxbury and Monadnock soils are loamy over sandy or gravelly; and Monadnock soils are underlain by till. 21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations due to very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations due to very bouldery or extremely stony surface conditions.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

CbD—Colton very gravelly loamy sand, 15 to 35 percent slopes, very bouldery

Setting

This soil is sandy and gravelly, very deep, moderately steep and steep, and excessively drained. It is on backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 5 to 75 acres in size.

Map Unit Composition

Major Components
Colton, very bouldery: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 4 percent
Monadnock: 3 percent
Unnamed: 3 percent

The somewhat excessively drained Adams, and well drained Duxbury and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy; Duxbury and Monadnock soils are loamy over sandy or gravelly; and Monadnock soils are underlain by till. Included areas can occupy about 15 percent of this unit.

0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 3 inches: rapid or very rapid (6 to 100 inches/hour)
3 to 6 inches: rapid or very rapid (6 to 100 inches/hour)
6 to 13 inches: rapid or very rapid (6 to 100 inches/hour)
13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture

- The slope may restrict the use of most farm equipment.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.

- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CgB—Cayuga silty clay loam, 3 to 8 percent slopes

Setting

This soil is clayey over loamy, very deep, gently sloping, and moderately well drained. It is on summits and shoulders of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 350 acres in size.

Map Unit Composition

Major Components
Cayuga: 85 percent

Inclusions
Churchville: 5 percent
Vergennes: 4 percent
Amenia: 2 percent
Massena: 2 percent
Unnamed: 2 percent

The somewhat poorly drained Churchville and Massena, Vergennes, and Amenia soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Churchville and Massena soils occupy slightly lower positions, and Massena soils are loamy. Vergennes soils occupy similar positions but are clayey. Amenia soils occupy similar positions but are loamy. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland (fig. 16)
Land capability classification: 2e
Hydric soil rating:
    Cayuga: no
Hydrologic group:
    Cayuga: C/D

Soil Properties and Qualities

Cayuga
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
    Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: very high
Surface runoff potential: very high
Landform: drumlinoid ridges
Parent material: not specified

Reaction (pH):
- 0 to 8 inches: moderately acid to neutral (5.6 to 7.3)
- 8 to 14 inches: moderately acid to neutral (5.6 to 7.3)
- 14 to 19 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 19 to 24 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 24 to 28 inches: slightly acid to moderately alkaline (6.1 to 8.4)
- 28 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)

Permeability:
- 0 to 8 inches: moderately slow or moderate (0.2 to 2 inches/hour)
- 8 to 14 inches: moderately slow or moderate (0.2 to 2 inches/hour)
- 14 to 19 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
- 19 to 24 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
- 24 to 28 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
- 28 to 72 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Figure 16.—View of prime and important agricultural areas in the town of Essex. The somewhat poorly drained Kingsbury clay occupies the flat-lying foreground in hayland. The area in strips of alfalfa hay and corn stubble is gently sloping, moderately well drained Cayuga silty clay loam. The ridgetop in pasture and farm woodlot is gently sloping, moderately well drained Amenia fine sandy loam. All three soils have seasonal high water tables that affect management practices.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Limiting construction and operation activities to dry or frozen ground conditions will help overcome limitations of haul roads and log landings caused by clayey soils.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

CgC—Cayuga silty clay loam, 8 to 15 percent slopes

Setting

This soil is clayey over loamy, very deep, strongly sloping, and moderately well drained. It is on backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 70 acres in size.

Map Unit Composition

Major Components
Cayuga: 85 percent

Inclusions
Churchville: 5 percent
Vergennes: 4 percent
Amenia: 3 percent
Unnamed: 2 percent
Massena: 1 percent

The somewhat poorly drained Churchville and Massena, Vergennes, and Amenia soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Churchville and Massena soils occupy slightly lower positions, and Massena soils are loamy. Vergennes soils occupy similar positions but are clayey. Amenia soils occupy similar positions but are loamy. Included areas make up about 15 percent of this unit.

Use and Management

Cropland

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Limiting construction and operation activities to dry or frozen ground conditions will help overcome limitations of haul roads and log landings caused by clayey soils.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by

seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

ChB—Champlain loamy sand, 3 to 8 percent slopes

Setting

This soil is sandy, very deep, gently sloping, and somewhat excessively drained. It is on summits and shoulders of deltas, outwash plains, and stream terraces in the Adirondack Upland. Areas range from 3 to 210 acres in size.

Map Unit Composition

Major Components
Champlain: 85 percent

Inclusions
Mooers: 5 percent
Adams: 4 percent

Colton: 3 percent
Fernlake: 2 percent
Nicholville: 1 percent

The moderately well drained Mooers and Nicholville, Adams, excessively drained Colton, and Fernlake soils may be included in areas of this map unit. Mooers and Nicholville soils occupy slightly lower positions, and Nicholville soils are silty and have a spodic horizon. Adams, Colton, and Fernlake soils occupy similar positions, but all have a spodic horizon; Colton soils are sandy and gravelly; and Fernlake soils are underlain by till. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: proglacial deltas, proglacial outwash plains, proglacial stream terraces
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 7 inches: strongly acid to slightly acid (5.1 to 6.5)
  7 to 10 inches: strongly acid to slightly acid (5.1 to 6.5)
  10 to 16 inches: strongly acid to slightly acid (5.1 to 6.5)
  16 to 24 inches: strongly acid to slightly acid (5.1 to 6.5)
  24 to 35 inches: moderately acid to neutral (5.6 to 7.3)
  35 to 50 inches: moderately acid to neutral (5.6 to 7.3)
  50 to 72 inches: moderately acid to neutral (5.6 to 7.3)
Permeability:
  0 to 7 inches: rapid (6 to 20 inches/hour)
  7 to 10 inches: rapid (6 to 20 inches/hour)
  10 to 16 inches: rapid (6 to 20 inches/hour)
  16 to 24 inches: rapid (6 to 20 inches/hour)
  24 to 35 inches: rapid (6 to 20 inches/hour)
  35 to 50 inches: rapid (6 to 20 inches/hour)
  50 to 72 inches: rapid (6 to 20 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

ChC—Champlain loamy sand, 8 to 15 percent slopes

- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment

of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

ChE—Champlain loamy sand, 25 to 45 percent slopes

Setting

This soil is sandy, very deep, very steep, and somewhat excessively drained. It is on backslopes of deltas, outwash plains, and stream terraces in the Adirondack Upland. Areas range from 3 to 95 acres in size.

Map Unit Composition

Major Components
Champlain: 85 percent

Inclusions
Adams: 4 percent
Colton: 4 percent
Fernlake: 3 percent
Monadnock: 2 percent
Nicholville: 2 percent

The Adams, excessively drained Colton, Fernlake, well drained Monadnock, and moderately well drained Nicholville soils may be included in areas of this map unit. Adams, Colton, Fernlake, and Monadnock soils occupy similar positions, but all have a spodic horizon; Colton soils are sandy and gravelly; Fernlake and Monadnock soils are underlain by till; and Monadnock soils have a loamy surface and subsoil. Nicholville soils are on drainageways and are silty and have a spodic horizon. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6e
Hydric soil rating:
  Champlain: no
Hydrologic group:
  Champlain: A

Soil Properties and Qualities

Champlain
Drainage class: somewhat excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: low

Shrink-swell potential: low
Surface runoff potential: low
Landform: proglacial deltas, proglacial outwash plains, proglacial stream terraces
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
 0 to 7 inches: strongly acid to slightly acid (5.1 to 6.5)
 7 to 10 inches: strongly acid to slightly acid (5.1 to 6.5)
 10 to 16 inches: strongly acid to slightly acid (5.1 to 6.5)
 16 to 24 inches: strongly acid to slightly acid (5.1 to 6.5)
 24 to 35 inches: moderately acid to neutral (5.6 to 7.3)
 35 to 50 inches: moderately acid to neutral (5.6 to 7.3)
 50 to 72 inches: moderately acid to neutral (5.6 to 7.3)
Permeability:
 0 to 7 inches: rapid (6 to 20 inches/hour)
 7 to 10 inches: rapid (6 to 20 inches/hour)
 10 to 16 inches: rapid (6 to 20 inches/hour)
 16 to 24 inches: rapid (6 to 20 inches/hour)
 24 to 35 inches: rapid (6 to 20 inches/hour)
 35 to 50 inches: rapid (6 to 20 inches/hour)
 50 to 72 inches: rapid (6 to 20 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.

• Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

• The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

• The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
• Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
• Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

• The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CkA—Charles silt loam, 0 to 2 percent slopes

Setting

This soil is silty, very deep, nearly level, and poorly drained. It is on flood plains in the Adirondack Upland. Areas range from 3 to 50 acres in size.

Map Unit Composition

Major Components
Charles: 85 percent

Inclusions
Cornish: 5 percent
Burnt Vly: 3 percent
Medomak: 3 percent
Rumney: 3 percent
Fluvaquents-Udifluvents: 1 percent

The somewhat poorly drained Cornish, very poorly drained Burnt Vly and Medomak, Rumney, and somewhat poorly and well drained Fluvaquents-Udifluvents may be included in areas of this map unit. Cornish soils occupy slightly higher positions. Burnt Vly and Medomak soils occupy lower positions on the flood plain, and Burnt Vly soils are mucky over sandy. Rumney soils occupy similar positions but are loamy. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 4w
Hydric soil rating:
    Charles: yes
Hydrologic group:
    Charles: A/D

Soil Properties and Qualities

Charles

Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent
  Flooding: frequent
  Available water capacity: high
  Potential frost action: high
  Shrink-swell potential: low
  Surface runoff potential: very high
  Landform: flood plains
  Parent material: silty alluvium derived from gneiss
Reaction (pH):
  0 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 16 inches: extremely acid to slightly acid (3.5 to 6.5)
  16 to 28 inches: extremely acid to slightly acid (3.5 to 6.5)
  28 to 38 inches: extremely acid to slightly acid (3.5 to 6.5)
  38 to 46 inches: extremely acid to slightly acid (3.5 to 6.5)
  46 to 52 inches: extremely acid to slightly acid (3.5 to 6.5)
  52 to 72 inches: extremely acid to slightly acid (3.5 to 6.5)
Permeability:
  0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 16 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  16 to 28 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  28 to 38 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  38 to 46 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  46 to 52 inches: moderate to rapid (0.6 to 20 inches/hour)
  52 to 72 inches: moderate to rapid (0.6 to 20 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland

- These soils are poorly suited to cultivated crops due to the seasonal high water table.
- Flooding may delay planting or damage crops in some years.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: In the CkA map unit has an A horizon that is thicker than the range of the Charles series. This should not significantly affect use and management on a local basis for most purposes.

ClB—Charlton gravelly fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and well drained. It is on summits and shoulders of glaciated hills in the Champlain Valley. Areas range from 5 to 185 acres in size.

Map Unit Composition

Major Components
Charlton: 85 percent

Inclusions
Georgia: 5 percent
Unnamed: 4 percent
Massena: 3 percent
Pittsfield: 2 percent
Chatfield: 1 percent

The moderately well drained Georgia, somewhat poorly drained Massena, Pittsfield, and Chatfield soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Georgia soils occupy slightly lower positions. Massena soils are on small depressions or drainageways. Pittsfield and Chatfield soils occupy similar positions, but Pittsfield soils have a higher pH, and Chatfield soils are moderately deep to bedrock. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e
Hydric soil rating:
Charlton: no
Hydrologic group:
Charlton: A

Soil Properties and Qualities

Charlton
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches

Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Landform: glaciated hills
Parent material: loamy ablation till derived from igneous and sedimentary rock
Reaction (pH):
0 to 5 inches: very strongly acid to moderately acid (4.5 to 6.0)
5 to 11 inches: very strongly acid to moderately acid (4.5 to 6.0)

11 to 19 inches: very strongly acid to moderately acid (4.5 to 6.0)
19 to 36 inches: very strongly acid to moderately acid (4.5 to 6.0)
36 to 45 inches: very strongly acid to moderately acid (4.5 to 6.0)
45 to 72 inches: very strongly acid to moderately acid (4.5 to 6.0)

Permeability:
0 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
11 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
19 to 36 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
36 to 45 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
45 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

ClC—Charlton gravelly fine sandy loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hills in the Champlain Valley. Areas range from 3 to 90 acres in size.

Map Unit Composition

Major Components
Charlton: 85 percent

Inclusions
Georgia: 5 percent
Pittsfield: 4 percent
Unnamed: 4 percent
Chatfield: 1 percent
Massena: 1 percent

The moderately well drained Georgia, somewhat poorly drained Massena, Pittsfield, and Chatfield soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Georgia soils occupy slightly lower positions. Massena soils are on small depressions or drainageways. Pittsfield and Chatfield soils occupy similar positions, but Pittsfield soils have a higher pH, and Chatfield soils are moderately deep to bedrock. Included areas make up about 15 percent of this unit.

    36 to 45 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
    45 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

ClD—Charlton gravelly fine sandy loam, 15 to 25 percent slopes

Setting

This soil is loamy, very deep, moderately steep, and well drained. It is on shoulders and backslopes of glaciated hills in the Champlain Valley. Areas range from 10 to 50 acres in size.

Map Unit Composition

Major Components
Charlton: 85 percent

Inclusions
Pittsfield: 6 percent
Unnamed: 5 percent
Chatfield: 3 percent
Georgia: 1 percent

The Pittsfield, Chatfield, and moderately well drained Georgia soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Pittsfield and Chatfield soils occupy similar positions, but Pittsfield soils have a higher pH, and Chatfield soils are moderately deep to bedrock. Georgia soils are on drainageways. Included areas make up about 15 percent of this unit.

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.

- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CnC—Charlton-Chatfield complex, 8 to 15 percent slopes, rocky, very stony

Setting

These soils are loamy, very deep and moderately deep, strongly sloping, and well drained. They are on shoulders and backslopes of glaciated hills in the Champlain Valley. Areas range from 3 to 45 acres in size.

Map Unit Composition

Major Components
Charlton, rocky, very stony: 45 percent
Chatfield, rocky, very stony: 30 percent

Inclusions
Hollis: 8 percent
Unnamed: 7 percent
Pittsfield: 5 percent
Georgia: 2 percent
Cayuga: 1 percent
Massena: 1 percent
Rock Outcrop: 1 percent

The Hollis, Pittsfield, moderately well drained Georgia and Cayuga, and somewhat poorly drained Massena soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Hollis and Pittsfield occupy similar positions, but Hollis soils are shallow to bedrock, and Pittsfield soils have a higher pH. Georgia and Cayuga soils occupy slightly lower positions, and Cayuga soils are clayey over loamy. Massena soils are on small depressions or drainageways. Included areas make up about 25 percent of this unit.

 19 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 27 to 32 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 32 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

CnD—Charlton-Chatfield complex, 15 to 35 percent slopes, rocky, very stony

Setting

These soils are loamy, very deep and moderately deep, moderately steep and steep, and well drained. They are on backslopes of glaciated hills in the Champlain Valley. Areas range from 3 to 240 acres in size.

Map Unit Composition

Major Components
Charlton, rocky, very stony: 45 percent
Chatfield, rocky, very stony: 30 percent

Inclusions
Hollis: 9 percent
Unnamed: 7 percent
Pittsfield: 6 percent
Cayuga: 1 percent
Georgia: 1 percent
Rock Outcrop: 1 percent

The Hollis, Pittsfield, and moderately well drained Georgia and Cayuga soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Hollis and Pittsfield occupy similar positions, but Hollis soils are shallow to bedrock, and Pittsfield soils have a higher pH. Georgia and Cayuga soils occupy slightly lower positions, and Cayuga soils are clayey over loamy. Included areas make up about 25 percent of this unit.

27 to 32 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
32 inches, bedrock

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of surface boulders and stones (fig. 17).

Pasture

- The slope may restrict the use of most farm equipment.
- Avoiding overgrazing can reduce the hazard of erosion.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Figure 17.—A road cut north of Wadhams in the town of Westport illustrates the anorthositic gneiss bedrock contact in Charlton-Chatfield map units. The moderately deep Chatfield soils are left of the tile spade, and the very deep Charlton soils are right of the spade. This map unit is an excellent timber producer, especially for White Pine, Red Pine, Northern Red Oak, and White Ash. Surface stoniness, rock outcrops, and steep slopes make it poor farmland.

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields

- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CoB—Chatfield-Hollis complex, 3 to 8 percent slopes, very rocky, very stony

Setting

These soils are loamy, moderately deep and shallow, gently sloping, and well drained. They are on summits and shoulders of glaciated hills in the Champlain Valley. Areas range from 3 to 105 acres in size.

Map Unit Composition

13 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations due to moderately deep and shallow soils.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

CoC—Chatfield-Hollis complex, 8 to 15 percent slopes, very rocky, very stony

Chatfield, very rocky, very stony
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none

Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 7 inches: very strongly acid to moderately acid (4.5 to 6.0)
  7 to 19 inches: very strongly acid to moderately acid (4.5 to 6.0)
  19 to 27 inches: very strongly acid to moderately acid (4.5 to 6.0)
  27 to 32 inches: very strongly acid to moderately acid (4.5 to 6.0)
  32 inches, bedrock
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  7 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  19 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  27 to 32 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  32 inches, bedrock

Hollis, very rocky, very stony
Drainage class: well drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 6 inches: very strongly acid to moderately acid (4.5 to 6.0)
  6 to 13 inches: very strongly acid to moderately acid (4.5 to 6.0)
  13 inches, bedrock
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  6 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  13 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.

- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by moderately deep and shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep and shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CpB—Churchville loam, 2 to 8 percent slopes

Setting

This soil is clayey over loamy, very deep, gently sloping, and somewhat poorly drained. It is on footslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 35 acres in size.

Map Unit Composition

Major Components
Churchville: 85 percent

Inclusions
Cayuga: 5 percent
Kingsbury: 4 percent
Massena: 3 percent
Unnamed: 2 percent
Covington: 1 percent

The moderately well drained Cayuga, Kingsbury, Massena, and poorly drained Covington soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Cayuga soils occupy slightly higher positions. Kingsbury and Massena soils occupy similar positions, but Kingsbury soils are clayey, and Massena soils are loamy. Covington soils are on small depressions and drainageways, and are clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
Churchville: no
Hydrologic group:
Churchville: C/D

Soil Properties and Qualities

Churchville
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 40 inches to densic material
Depth to seasonal high water table: 6 to 18 inches
Water table kind: perched
Flooding: none
Available water capacity: low to moderate
Potential frost action: high
Shrink-swell potential: very high
Surface runoff potential: very high
Landform: drumlinoid ridges
Parent material: clayey glaciolacustrine deposits derived from igneous and sedimentary rock over loamy lodgment till derived from limestone
Reaction (pH):
0 to 9 inches: moderately acid to neutral (5.6 to 7.3)
9 to 13 inches: slightly acid to slightly alkaline (6.1 to 7.8)
13 to 25 inches: slightly acid to slightly alkaline (6.1 to 7.8)

25 to 35 inches: slightly alkaline to strongly alkaline (7.4 to 9.0)
35 to 48 inches: slightly alkaline to strongly alkaline (7.4 to 9.0)
48 to 72 inches: slightly alkaline to strongly alkaline (7.4 to 9.0)

Permeability:
0 to 9 inches: moderately slow or moderate (0.2 to 2 inches/hour)
9 to 13 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
13 to 25 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
25 to 35 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
35 to 48 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
48 to 72 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Limiting construction and operation activities to dry or frozen ground conditions will help overcome limitations of haul roads and log landings caused by clayey soils.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

CqA—Claverack loamy fine sand, 0 to 3 percent slopes

Setting

This soil is sandy over clayey, very deep, nearly level, and moderately well drained. It is on summits and shoulders of lake plains in the Champlain Valley. Areas range from 4 to 30 acres in size.

Map Unit Composition

Major Components
Claverack: 85 percent

Inclusions
Cosad: 5 percent
Elmridge: 4 percent
Deerfield: 2 percent
Unnamed: 2 percent

Vergennes: 1 percent
Windsor: 1 percent

The somewhat poorly drained Cosad, Elmridge, Deerfield, Vergennes, and excessively drained Windsor soils may be included in areas of this map unit. Also included are small areas of well drained sandy over clayey soils. Cosad soils occupy slightly lower positions. Elmridge, Deerfield, and Vergennes soils occupy similar positions, but Elmridge soils are loamy over clayey; Deerfield soils are sandy; and Vergennes soils are clayey. Windsor soils occupy higher positions, and are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland

Depth to root-restrictive feature: 20 to 40 inches to strongly contrasting textural stratification
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: perched
Flooding: none
Available water capacity: very low to low
Potential frost action: moderate
Shrink-swell potential: very high
Surface runoff potential: low
Landform: lake plains
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock over clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 12 inches: strongly acid to neutral (5.1 to 7.3)
  12 to 16 inches: strongly acid to neutral (5.1 to 7.3)
  16 to 22 inches: strongly acid to neutral (5.1 to 7.3)
  22 to 26 inches: strongly acid to neutral (5.1 to 7.3)
  26 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
  0 to 12 inches: moderately rapid or rapid (2 to 20 inches/hour)
  12 to 16 inches: rapid (6 to 20 inches/hour)
  16 to 22 inches: rapid (6 to 20 inches/hour)
  22 to 26 inches: rapid (6 to 20 inches/hour)
  26 to 72 inches: very slow or slow (0.001 to 0.2 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.

- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

CqB—Claverack loamy fine sand, 3 to 8 percent slopes

Setting

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.

- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

CrB—Collamer silt loam, 2 to 8 percent slopes

Setting

This soil is silty and clayey, very deep, gently sloping, and moderately well drained. It is on summits and shoulders of lake plains in the Champlain Valley. Areas range from 3 to 70 acres in size.

Map Unit Composition

Major Components
Collamer: 85 percent

Inclusions
Dunkirk: 5 percent
Niagara: 3 percent
Cayuga: 2 percent
Hartland: 2 percent
Unnamed: 2 percent
Factoryville: 1 percent

The well drained Dunkirk, Hartland, and Factoryville, somewhat poorly drained Niagara, and Cayuga soils may be included in areas of this map unit. Also included are areas that have a slightly higher clay content. Dunkirk, Hartland, and Factoryville soils occupy slightly higher positions; Hartland soils are silty; and Factoryville soils are sandy. Niagara soils occupy slightly lower positions. Cayuga soils occupy similar positions, but are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e
Hydric soil rating:
    Collamer: no
Hydrologic group:
    Collamer: C/D

Soil Properties and Qualities

Collamer
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
    Water table kind: apparent
Flooding: none

11 to 16 inches: moderately slow or moderate (0.2 to 2 inches/hour)
16 to 25 inches: slow to moderate (0.06 to 2 inches/hour)
25 to 35 inches: slow to moderate (0.06 to 2 inches/hour)
35 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland

- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

Correlation Note: The CrB map unit has a B horizon that has a color value darker than typical for the range of the Collamer series. This should not significantly affect use and management on a local basis for most purposes.

CsA—Colton very gravelly loamy sand, 0 to 3 percent slopes

Setting

This soil is sandy and gravelly, very deep, nearly level, and excessively drained. It is on summits of kame terraces and outwash plains in the Adirondack Upland. Areas range from 4 to 345 acres in size.

Map Unit Composition

Major Components
Colton: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 3 percent

Unnamed: 3 percent
Croghan: 2 percent
Monadnock: 2 percent

The somewhat excessively drained Adams, well drained Duxbury and Monadnock, and moderately well drained Croghan soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy, Duxbury and Monadnock soils are loamy over sandy or gravelly, and Monadnock soils are underlain by till. Croghan soils are in small depressions or along drainageways, and are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance

  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: rapid or very rapid (6 to 100 inches/hour)
  3 to 6 inches: rapid or very rapid (6 to 100 inches/hour)
  6 to 13 inches: rapid or very rapid (6 to 100 inches/hour)
  13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
  21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

CsB—Colton very gravelly loamy sand, 3 to 8 percent slopes

Setting

This soil is sandy and gravelly, very deep, gently sloping, and excessively drained. It is on summits and shoulders of kame terraces and outwash plains in the Adirondack Upland. Areas range from 3 to 340 acres in size.

Map Unit Composition

Major Components
Colton: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 4 percent
Unnamed: 3 percent
Monadnock: 2 percent

  13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
  21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

CsC—Colton very gravelly loamy sand, 8 to 15 percent slopes

Setting

This soil is sandy and gravelly, very deep, strongly sloping, and excessively drained. It is on shoulders and backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 3 to 120 acres in size.

Map Unit Composition

Major Components
Colton: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 4 percent
Monadnock: 3 percent
Unnamed: 3 percent

The somewhat excessively drained Adams, and well drained Duxbury and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy; Duxbury and Monadnock soils are loamy over sandy or gravelly; and Monadnock soils are underlain by till. Included areas can occupy about 15 percent of this unit.

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

CsD—Colton very gravelly loamy sand, 15 to 25 percent slopes

Setting

This soil is sandy and gravelly, very deep, moderately steep, and excessively drained. It is on backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 3 to 50 acres in size.

Map Unit Composition

Major Components
Colton: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 4 percent
Monadnock: 3 percent
Unnamed: 3 percent

The somewhat excessively drained Adams, and well drained Duxbury and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy; Duxbury and Monadnock soils are loamy over

sandy or gravelly; and Monadnock soils are underlain by till. Included areas can occupy about 15 percent of this unit.

13 to 21 inches: rapid or very rapid (6 to 100 inches/hour)
21 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage

structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CsE—Colton very gravelly loamy sand, 25 to 45 percent slopes

Setting

This soil is sandy and gravelly, very deep, very steep, and excessively drained. It is on backslopes of kame terraces and outwash plains in the Adirondack Upland. Areas range from 3 to 70 acres in size.

Map Unit Composition

Major Components
Colton: 85 percent

Inclusions
Adams: 5 percent
Duxbury: 4 percent
Monadnock: 3 percent
Unnamed: 3 percent

The somewhat excessively drained Adams, and well drained Duxbury and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Adams, Duxbury, and Monadnock soils occupy similar positions, but Adams soils are sandy; Duxbury and Monadnock soils are loamy over sandy or gravelly; and Monadnock soils are underlain by till. - Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

CtA—Cornish silt loam, 0 to 2 percent slopes

Setting

This soil is silty, very deep, nearly level, and somewhat poorly drained. It is on flood plains in the Adirondack Upland. Areas range from 5 to 55 acres in size.

Map Unit Composition

Major Components
Cornish: 85 percent

Inclusions
Lovewell: 5 percent
Charles: 3 percent
Medomak: 2 percent
Podunk: 2 percent
Rumney: 2 percent
Fluvaquents-Udifluvents: 1 percent

The moderately well drained Lovewell and Podunk, poorly drained Charles and Rumney, very poorly drained Medomak, and somewhat poorly drained and well drained Fluvaquents-Udifluvents may be included in areas of this map unit. Lovewell and Podunk soils occupy slightly higher positions, and Podunk soils are loamy. Charles, Medomak, and Rumney soils occupy lower positions on the flood plain, and Rumney soils are loamy. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
    Cornish: no

    Cornish: B/D

Soil Properties and Qualities

Cornish
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
    Water table kind: apparent
Flooding: occasional
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: flood plains
Parent material: silty alluvium derived from gneiss
Reaction (pH):
    0 to 12 inches: very strongly acid to slightly acid (4.5 to 6.5)
    12 to 21 inches: very strongly acid to slightly acid (4.5 to 6.5)
    21 to 35 inches: very strongly acid to slightly acid (4.5 to 6.5)
    35 to 42 inches: very strongly acid to slightly acid (4.5 to 6.5)
    42 to 48 inches: very strongly acid to slightly acid (4.5 to 6.5)
    48 to 53 inches: very strongly acid to slightly acid (4.5 to 6.5)
    53 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
    0 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    12 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    21 to 35 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

35 to 42 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
42 to 48 inches: moderate to rapid (0.6 to 20 inches/hour)
48 to 53 inches: moderate to rapid (0.6 to 20 inches/hour)
53 to 72 inches: moderate to rapid (0.6 to 20 inches/hour)

Use and Management

Cropland

- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- Flooding may delay planting or damage crops in some years.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

CuA—Cosad loamy fine sand, 0 to 3 percent slopes

Setting

This soil is sandy over clayey, very deep, nearly level, and somewhat poorly drained. It is on summits and shoulders of lake plains in the Champlain Valley. Areas range from 3 to 85 acres in size.

Map Unit Composition

Major Components
Cosad: 85 percent

Inclusions
Claverack: 4 percent
Stafford: 4 percent
Unnamed: 3 percent
Kingsbury: 2 percent
Elmridge: 1 percent
Gougeville: 1 percent

The moderately well drained Claverack and Elmridge, Stafford, Kingsbury, and poorly drained Gougeville soils may be included in areas of this map unit. Also included are small areas of poorly drained sandy over clayey soils. Claverack and Elmridge soils occupy slightly higher positions, and Elmridge soils are loamy over clayey. Stafford and Kingsbury soils occupy similar positions, but Stafford soils are sandy, and Kingsbury soils are clayey. Gougeville soils are on small depressions and are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
Cosad: no
Hydrologic group:
Cosad: C/D

Soil Properties and Qualities

Cosad
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 18 to 40 inches to strongly contrasting textural stratification
Depth to seasonal high water table: 6 to 18 inches
Water table kind: perched
Flooding: none
Available water capacity: very low to low
Potential frost action: moderate
Shrink-swell potential: very high
Surface runoff potential: very high
Landform: lake plains
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock over clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
0 to 12 inches: strongly acid to slightly acid (5.1 to 6.5)
12 to 18 inches: strongly acid to neutral (5.1 to 7.3)
18 to 23 inches: strongly acid to neutral (5.1 to 7.3)
23 to 25 inches: moderately acid to slightly alkaline (5.6 to 7.8)
25 to 39 inches: neutral or slightly alkaline (6.6 to 7.8)
39 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
0 to 12 inches: moderately rapid or rapid (2 to 20 inches/hour)
12 to 18 inches: rapid (6 to 20 inches/hour)
18 to 23 inches: rapid (6 to 20 inches/hour)
23 to 25 inches: rapid (6 to 20 inches/hour)
25 to 39 inches: very slow or slow (0.001 to 0.2 inches/hour)
39 to 72 inches: very slow or slow (0.001 to 0.2 inches/hour)

Use and Management

Cropland

- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture

- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause foundations to shift and basement walls and floors to crack.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The moderate to slow rate of fluid movement through parts of these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

Correlation Note: The CuA and CuB map units are taxadjuncts to the Cosad series because the pedon qualifies as having a Cambic horizon in the 2BC horizon. The classification of the taxadjunct is Sandy over clayey, mixed, superactive, mesic Aquic Eutrudepts. The classification of Cosad is Sandy over clayey, mixed, superactive, nonacid, mesic Aquic Udorthents. This should not significantly affect use and management on a local basis for most purposes.

CuB—Cosad loamy fine sand, 3 to 8 percent slopes

Setting

This soil is sandy over clayey, very deep, gently sloping, and somewhat poorly drained. It is on summits and shoulders of lake plains in the Champlain Valley. Areas range from 3 to 70 acres in size.

Map Unit Composition

Major Components
Cosad: 85 percent

Inclusions
Claverack: 5 percent
Stafford: 4 percent
Unnamed: 3 percent
Kingsbury: 2 percent
Elmridge: 1 percent

The moderately well drained Claverack and Elmridge, Stafford, and Kingsbury soils may be included in areas of this map unit. Also included are small areas of poorly drained sandy over clayey soils. Claverack and Elmridge soils occupy slightly higher

positions, and Elmridge soils are loamy over clayey. Stafford and Kingsbury soils occupy similar positions, but Stafford soils are sandy; and Kingsbury soils are clayey. Included areas can occupy about 15 percent of this unit.

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in parts of these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.

- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The moderate to slow rate of fluid movement through parts of these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

Correlation Note: The CuA and CuB map units are taxadjuncts to the Cosad series because the pedon qualifies as having a Cambic horizon in the 2BC horizon. The classification of the taxadjunct is Sandy over clayey, mixed, superactive, mesic Aquic Eutrudepts. The classification of Cosad is Sandy over clayey, mixed, superactive, nonacid, mesic Aquic Udorthents. This should not significantly affect use and management on a local basis for most purposes.

CvA—Covington clay, 0 to 3 percent slopes

Setting

This soil is clayey, very deep, nearly level, and poorly drained. It is on toeslopes of lake plains in the Champlain Valley. Areas range from 3 to 160 acres in size.

Map Unit Composition

Major Components
Covington: 85 percent

Inclusions
Kingsbury: 5 percent
Livingston: 4 percent
Churchville: 3 percent
Whallonsburg: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Kingsbury and Churchville, and very poorly drained Livingston and Whallonsburg soils may be included in areas of this map unit. Also included are areas of poorly drained soils that have a slightly lower clay content. Kingsbury and Churchville soils occupy slightly higher positions, but Churchville soils are clayey over loamy. Livingston and Whallonsburg soils occupy slightly lower positions, but Whallonsburg soils are mucky over clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

Land capability classification: 4w
Hydric soil rating:
  Covington: yes
Hydrologic group:
  Covington: D

Soil Properties and Qualities

Covington
Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: very high
Surface runoff potential: very high
Landform: lake plains
Parent material: clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 9 inches: moderately acid to neutral (5.6 to 7.3)
  9 to 19 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  19 to 24 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  24 to 36 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  36 to 72 inches: moderately acid to moderately alkaline (5.6 to 8.4)
Permeability:
  0 to 9 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
  9 to 19 inches: very slow or slow (0.001 to 0.2 inches/hour)
  19 to 24 inches: very slow or slow (0.001 to 0.2 inches/hour)
  24 to 36 inches: very slow or slow (0.001 to 0.2 inches/hour)
  36 to 72 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are poorly suited to cultivated crops caused by the seasonal high water table.
- The root system of some deep-rooted crops may be damaged by frost action.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.

- Limiting construction activities to dry or frozen ground conditions will help overcome construction limitations of haul roads caused by clayey soils.
- Areas of poorly drained and very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause foundations to shift and basement walls and floors to crack.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

CwA—Croghan fine sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and moderately well drained. It is on footslopes of deltas, outwash plains, and stream terraces in the Adirondack Upland. Areas range from 3 to 80 acres in size.

Map Unit Composition

Major Components
Croghan: 85 percent

Inclusions
Naumburg: 5 percent
Adams: 3 percent
Mooers: 3 percent
Searsport: 2 percent
Unnamed: 2 percent

The somewhat poorly drained Naumburg, somewhat excessively drained Adams, Mooers, and very poorly drained Searsport soils may be included in areas of this map unit. Also included are small areas of poorly drained sandy soils. Naumburg soils occupy slightly lower positions. Adams soils occupy higher positions. Mooers soils occupy similar positions, but lack a spodic horizon. Searsport soils are on small depressions or drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 2w
Hydric soil rating:
  Croghan: no

  Croghan: A/D

Soil Properties and Qualities

Croghan
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: deltas, outwash plains, stream terraces
Parent material: sandy glaciolacustrine deposits derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
  3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
  5 to 8 inches: very strongly acid to moderately acid (4.5 to 6.0)
  8 to 14 inches: very strongly acid to moderately acid (4.5 to 6.0)
  14 to 23 inches: very strongly acid to moderately acid (4.5 to 6.0)
  23 to 29 inches: very strongly acid to moderately acid (4.5 to 6.0)

29 to 42 inches: very strongly acid to moderately acid (4.5 to 6.0)
42 to 45 inches: very strongly acid to moderately acid (4.5 to 6.0)
45 to 72 inches: very strongly acid to moderately acid (4.5 to 6.0)

Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
3 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
5 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
8 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
23 to 29 inches: moderately rapid to very rapid (2 to 100 inches/hour)
29 to 42 inches: moderately rapid to very rapid (2 to 100 inches/hour)
42 to 45 inches: moderately rapid to very rapid (2 to 100 inches/hour)
45 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland

- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Applying gravel base material to log landings during construction and operation will help overcome limitations caused by sandy surfaces.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Maintaining a vegetative cover or spreading slash over exposed soil areas will help overcome harvest equipment operability limitations caused by sandy surfaces.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional

wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse-grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Applying gravel base material to log landings during construction and operation will help overcome limitations caused by sandy surfaces.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Maintaining a vegetative cover or spreading slash over exposed soil areas will help overcome harvest equipment operability limitations caused by sandy surfaces.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

DeA—Deerfield loamy sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and moderately well drained. It is on footslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 250 acres in size.

Map Unit Composition

Major Components
Deerfield: 85 percent

Inclusions
Stafford: 5 percent
Windsor: 4 percent
Claverack: 3 percent
Factoryville: 2 percent
Cosad: 1 percent

The somewhat poorly drained Stafford and Cosad, excessively drained Windsor, Claverack, and well drained Factoryville soils may be included in areas of this map unit. Stafford and Cosad soils occupy slightly lower positions, and Cosad soils are sandy over clayey. Windsor and Factoryville soils occupy higher positions, and Factoryville soils have finer sand textures. Claverack soils occupy similar positions, but are sandy over clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3w
Hydric soil rating:
  Deerfield: no
Hydrologic group:
  Deerfield: A/D

Soil Properties and Qualities

Deerfield
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches

Depth to seasonal high water table: 18 to 30 inches
    Water table kind: apparent
Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
    0 to 10 inches: very strongly acid to slightly acid (4.5 to 6.5)
    10 to 15 inches: very strongly acid to slightly acid (4.5 to 6.5)
    15 to 30 inches: very strongly acid to slightly acid (4.5 to 6.5)
    30 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
    0 to 10 inches: moderately rapid or rapid (2 to 20 inches/hour)
    10 to 15 inches: rapid (6 to 20 inches/hour)
    15 to 30 inches: rapid (6 to 20 inches/hour)
    30 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland

- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture

- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

Correlation Note: The DeA and DeB map units have moderate structure in the Ap horizon which is stronger than allowed in the range of the Deerfield series. This should not significantly affect use and management on a local basis for most purposes.

DeB—Deerfield loamy sand, 3 to 8 percent slopes

Setting

This soil is sandy, very deep, gently sloping, and moderately well drained. It is on footslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 35 acres in size.

Map Unit Composition

Major Components
Deerfield: 85 percent

Inclusions
Stafford: 5 percent
Windsor: 4 percent
Claverack: 3 percent
Factoryville: 2 percent
Cosad: 1 percent

The somewhat poorly drained Stafford and Cosad, excessively drained Windsor, Claverack, and well drained Factoryville soils may be included in areas of this map unit. Stafford and Cosad soils occupy slightly lower positions and Cosad soils are sandy over clayey. Windsor and Factoryville soils occupy higher positions, and Factoryville soils have finer sand textures. Claverack soils occupy similar positions, but are sandy over clayey. Included areas can occupy about 15 percent of this unit.

15 to 30 inches: rapid (6 to 20 inches/hour)
30 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.

- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

Correlation Note: The DeA and DeB map units have moderate structure in the Ap horizon which is stronger than allowed in the range of the Deerfield series. This should not significantly affect use and management on a local basis for most purposes.

DpC—Depeyster silt loam, 8 to 15 percent slopes

Setting

This soil is silty and clayey, very deep, strongly sloping, and moderately well drained. It is on shoulders and backslopes of glacial-valley walls in the Adirondack Upland. Areas range from 3 to 90 acres in size.

Map Unit Composition

Major Components
Depeyster: 85 percent

Inclusions
Hailesboro: 5 percent
Nicholville: 4 percent
Champlain: 3 percent
Roundabout: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Hailesboro and Roundabout, Nicholville, and somewhat excessively drained Champlain soils may be included in areas of this map unit. Also included are well drained areas of silty and clayey soils. Hailesboro and Roundabout soils occupy slightly lower positions, and Roundabout soils are silty. Nicholville soils occupy similar positions, but are silty. Champlain soils occupy higher positions, and are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3e
Hydric soil rating:
  Depeyster: no
Hydrologic group:
  Depeyster: C/D

Soil Properties and Qualities

Depeyster
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: moderate
Surface runoff potential: very high
Landform: glacial-valley walls
Parent material: silty glaciolacustrine deposits derived from igneous and sedimentary rock

Reaction (pH):
- 0 to 4 inches: moderately acid to neutral (5.6 to 7.3)
- 4 to 7 inches: strongly acid to neutral (5.1 to 7.3)
- 7 to 13 inches: slightly acid or neutral (6.1 to 7.3)
- 13 to 18 inches: slightly acid to slightly alkaline (6.1 to 7.8)
- 18 to 25 inches: slightly acid to slightly alkaline (6.1 to 7.8)
- 25 to 31 inches: neutral to moderately alkaline (6.6 to 8.4)
- 31 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)

Permeability:
- 0 to 4 inches: moderate (0.6 to 2 inches/hour)
- 4 to 7 inches: moderate (0.6 to 2 inches/hour)
- 7 to 13 inches: slow to moderate (0.06 to 2 inches/hour)
- 13 to 18 inches: slow to moderate (0.06 to 2 inches/hour)
- 18 to 25 inches: slow to moderate (0.06 to 2 inches/hour)
- 25 to 31 inches: slow to moderate (0.06 to 2 inches/hour)
- 31 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.

- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

DpD—Depeyster silt loam, 15 to 25 percent slopes

Setting

This soil is silty and clayey, very deep, moderately steep, and moderately well drained. It is on backslopes of glacial-valley walls in the Adirondack Upland. Areas range from 4 to 105 acres in size.

Map Unit Composition

Major Components
Depeyster: 85 percent

Inclusions
Nicholville: 6 percent
Hailesboro: 4 percent
Champlain: 3 percent
Unnamed: 2 percent

The Nicholville, somewhat poorly drained Hailesboro, and somewhat excessively drained Champlain soils may be included in areas of this map unit. Also included are well drained areas of silty and clayey soils. Nicholville soils occupy similar positions, but are silty. Hailesboro soils occupy slightly lower positions. Champlain soils occupy higher positions, and are sandy. Included areas can occupy about 15 percent of this unit.

31 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

DuC—Dunkirk silt loam, 8 to 15 percent slopes

Setting

This soil is silty and clayey, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of lake plains in the Champlain Valley. Areas range from 3 to 125 acres in size.

Map Unit Composition

Major Components
Dunkirk: 85 percent

Inclusions
Collamer: 3 percent
Hartland: 3 percent
Cayuga: 2 percent

Elmridge: 2 percent
Factoryville: 2 percent
Niagara: 2 percent
Unnamed: 1 percent

The moderately well drained Collamer, Cayuga, and Elmridge, Hartland, Factoryville, and somewhat poorly drained Niagara soils may be included in areas of this map unit. Also included are areas that have a slightly higher clay content. Collamer, Cayuga, and Elmridge soils occupy slightly lower positions; Cayuga soils are clayey over loamy; and Elmridge soils are loamy over clayey. Hartland and Factoryville soils occupy similar positions, but Hartland soils are silty; and Factoryville soils are sandy. Niagara soils are on small depressions and drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

  35 to 42 inches: slow to moderate (0.06 to 2 inches/hour)
  42 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The potential for shrink-swell in these soils results in a limited capacity to support a load without movement and may cause shifting foundations and cracking of basement walls and floors.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

DuD—Dunkirk silt loam, 15 to 25 percent slopes

Setting

This soil is silty and clayey, very deep, moderately steep, and well drained. It is on backslopes of lake plains in the Champlain Valley. Areas range from 3 to 110 acres in size.

Map Unit Composition

Major Components
Dunkirk: 85 percent

Inclusions
Hartland: 5 percent
Factoryville: 3 percent
Vergennes: 3 percent
Collamer: 2 percent
Unnamed: 2 percent

The Hartland, Factoryville, and moderately well drained Vergennes and Collamer soils may be included in areas of this map unit. Also included are areas that have a slightly higher clay content. Hartland and Factoryville soils occupy similar positions, but Hartland soils are silty, and Factoryville soils are sandy. Collamer and Vergennes soils occupy slightly lower positions, and Vergennes soils are clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

35 to 42 inches: slow to moderate (0.06 to 2 inches/hour)
42 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The potential for shrink-swell in these soils results in a limited capacity to support a load without movement and may cause shifting foundations and cracking of basement walls and floors.

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

DuE—Dunkirk silt loam, 25 to 45 percent slopes

Setting

This soil is silty and clayey, very deep, very steep, and well drained. It is on backslopes of lake plains in the Champlain Valley. Areas range from 5 to 265 acres in size.

Map Unit Composition

Major Components
Dunkirk: 85 percent

Inclusions

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining

properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
• Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
• Erosion and sediment control can be severe problems where this map unit is cleared for development.
• Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
• The potential for shrink-swell in these soils results in a limited capacity to support a load without movement and may cause foundations to shift and basement walls and floors to crack.
• The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
• The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
• Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
• Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
• Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
• Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
• The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
• The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

DxB—Duxbury fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy over sandy and gravelly, very deep, gently sloping, and well drained. It is on summits and shoulders of outwash terraces in the Adirondack Upland. Areas range from 3 to 135 acres in size.

Map Unit Composition

Major Components
Duxbury: 85 percent

Inclusions
Colton: 5 percent
Adams: 4 percent

Champlain: 2 percent
Unnamed: 2 percent
Croghan: 1 percent
Monadnock: 1 percent

The excessively drained Colton, somewhat excessively drained Adams and Champlain, moderately well drained Croghan, and Monadnock soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Colton, Adams, Champlain, and Monadnock soils occupy similar positions, but Colton soils are sandy and gravelly; Adams and Champlain soils are sandy and Champlain soils lack a spodic horizon; and Monadnock soils are underlain by till. Croghan soils are on small depressions or drainageways, and are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e
Hydric soil rating:
  Duxbury: no
Hydrologic group:
  Duxbury: A

Soil Properties and Qualities

Duxbury
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate to high
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: low
Landform: outwash terraces
Parent material: loamy lacustrine deposits over gravelly outwash derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 4 inches: extremely acid to slightly acid (3.5 to 6.5)
  4 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 13 inches: extremely acid to slightly acid (3.5 to 6.5)
  13 to 21 inches: extremely acid to slightly acid (3.5 to 6.5)
  21 to 31 inches: very strongly acid to slightly acid (4.5 to 6.5)
  31 to 36 inches: very strongly acid to slightly acid (4.5 to 6.5)
  36 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  13 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  21 to 31 inches: very rapid (20 to 100 inches/hour)
  31 to 36 inches: very rapid (20 to 100 inches/hour)
  36 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

ElB—Elmridge fine sandy loam, 2 to 8 percent slopes

Setting

This soil is loamy over clayey, very deep, gently sloping, and moderately well drained. It is on summits and shoulders of lake plains in the Champlain Valley. Areas range from 3 to 90 acres in size.

Map Unit Composition

Major Components
Elmridge: 85 percent

Inclusions
Claverack: 5 percent
Unnamed: 4 percent
Cosad: 2 percent

Kingsbury: 2 percent
Niagara: 1 percent
Vergennes: 1 percent

The Claverack, Vergennes, and the somewhat poorly drained Cosad and Kingsbury and Niagara soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained loamy over clayey soils. Claverack and Vergennes soils occupy similar positions, but Claverack soils are sandy over clayey; and Vergennes soils are clayey. Cosad, Kingsbury, and Niagara soils occupy slightly lower positions, and Cosad soils are sandy over clayey, Kingsbury soils are clayey, and Niagara soils are silty and clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e
Hydric soil rating:
Elmridge: no
Hydrologic group:
Elmridge: C/D

Soil Properties and Qualities

Elmridge
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 18 to 40 inches to strongly contrasting textural stratification
Depth to seasonal high water table: 18 to 30 inches
Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: very high
Surface runoff potential: low
Landform: lake plains
Parent material: loamy glaciolacustrine deposits derived from igneous and sedimentary rock over clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
0 to 8 inches: very strongly acid to neutral (4.5 to 7.3)
8 to 15 inches: strongly acid to neutral (5.1 to 7.3)
15 to 25 inches: strongly acid to neutral (5.1 to 7.3)
25 to 31 inches: strongly acid to neutral (5.1 to 7.3)
31 to 46 inches: moderately acid to slightly alkaline (5.6 to 7.8)
46 to 72 inches: moderately acid to slightly alkaline (5.6 to 7.8)
Permeability:
0 to 8 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
8 to 15 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
15 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
25 to 31 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
31 to 46 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
46 to 72 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause foundations to shift and basement walls and floors to crack.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

FaD—Farmington loam, 15 to 35 percent slopes, very rocky, very stony

Setting

This soil is loamy, shallow, moderately steep and steep, and well drained. It is on backslopes of glaciated hills in the Champlain Valley. Areas range from 3 to 55 acres in size.

Map Unit Composition

Major Components
Farmington, very rocky, very stony: 85 percent

Inclusions
Rock Outcrop: 9 percent
Galway: 2 percent
Amenia: 1 percent
Nellis: 1 percent
Unnamed: 1 percent
Vergennes: 1 percent

The Galway, Nellis, and moderately well drained Amenia and Vergennes soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Galway and Nellis soils occupy similar positions, but Galway soils are moderately deep to bedrock, and Nellis soils are very deep. Amenia and Vergennes soils occupy slightly lower positions and are both very deep. Vergennes soils are clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
    Farmington, very rocky, very stony: no
Hydrologic group:
    Farmington, very rocky, very stony: D

Soil Properties and Qualities

Farmington, very rocky, very stony
Drainage class: well drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony

Landform: glaciated hills
Parent material: loamy till derived from limestone
Reaction (pH):
 0 to 6 inches: strongly acid to neutral (5.1 to 7.3)
 6 to 13 inches: moderately acid to slightly alkaline (5.6 to 7.8)
 13 inches, bedrock
Permeability:
 0 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 6 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 13 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture
- The slope may restrict the use of most farm equipment.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of

excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

FcB—Factoryville-Colonie complex, 3 to 8 percent slopes

Setting

These soils are sandy, very deep, gently sloping, and well drained to somewhat excessively drained. They are on summits and shoulders of proglacial deltas in the Champlain Valley. Areas range from 5 to 155 acres in size.

Map Unit Composition

Major Components
Factoryville: 45 percent
Colonie, calcareous substratum: 30 percent

Inclusions
Deerfield: 8 percent
Dunkirk: 5 percent
Hartland: 5 percent
Howard: 3 percent
Elmridge: 2 percent
Unnamed: 2 percent

The moderately well drained Deerfield and Elmridge, Dunkirk, Hartland, and Howard soils may be included in areas of this map unit. Also included are small areas of moderately well drained silty soils. Deerfield and Elmridge soils occupy slightly lower positions, and Elmridge soils are loamy over clayey. Dunkirk, Hartland, and Howard soils occupy similar positions, but Dunkirk soils are silty and clayey; Hartland soils are silty; and Howard soils are loamy and gravelly. Included areas can occupy about 25 percent of this unit.

Surface runoff potential: very low
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 11 inches: moderately acid to neutral (5.6 to 7.3)
  11 to 19 inches: strongly acid to neutral (5.1 to 7.3)
  19 to 29 inches: strongly acid to neutral (5.1 to 7.3)
  29 to 33 inches: strongly acid to neutral (5.1 to 7.3)
  33 to 65 inches: moderately acid to neutral (5.6 to 7.3)
  65 to 72 inches: moderately acid to neutral (5.6 to 7.3)
Permeability:
  0 to 11 inches: rapid (6 to 20 inches/hour)
  11 to 19 inches: rapid (6 to 20 inches/hour)
  19 to 29 inches: rapid (6 to 20 inches/hour)
  29 to 33 inches: rapid (6 to 20 inches/hour)
  33 to 65 inches: rapid (6 to 20 inches/hour)
  65 to 72 inches: rapid (6 to 20 inches/hour)

Colonie, calcareous substratum
Drainage class: somewhat excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock

Reaction (pH):
- 0 to 9 inches: very strongly acid to neutral (4.5 to 7.3)
- 9 to 14 inches: very strongly acid to neutral (4.5 to 7.3)
- 14 to 25 inches: very strongly acid to neutral (4.5 to 7.3)
- 25 to 37 inches: very strongly acid to neutral (4.5 to 7.3)
- 37 to 49 inches: very strongly acid to neutral (4.5 to 7.3)
- 49 to 56 inches: strongly acid to moderately alkaline (5.1 to 8.4)
- 56 to 61 inches: strongly acid to moderately alkaline (5.1 to 8.4)
- 61 to 72 inches: strongly acid to moderately alkaline (5.1 to 8.4)

Permeability:
- 0 to 9 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 9 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 14 to 25 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 25 to 37 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 37 to 49 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 49 to 56 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 56 to 61 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 61 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity (fig. 18).

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table in some areas of this map unit may severely limit the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Figure 18.—Good alfalfa production on a flat terrace of Factoryville and Colonie soils in the town of Crown Point. Native fertility of these loamy sands is good, but plants may suffer moisture stress (drought) in some years toward the end of the growing season.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of this map unit may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table in some areas of this map unit may impede excavation and grading and reduce the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

FcC—Factoryville-Colonie complex, 8 to 15 percent slopes

Setting

These soils are sandy, very deep, strongly sloping, and well drained to somewhat excessively drained. They are on shoulders and backslopes of proglacial deltas in the Champlain Valley. Areas range from 5 to 55 acres in size.

Map Unit Composition

Major Components
Factoryville: 45 percent
Colonie, calcareous substratum: 30 percent

Inclusions
Deerfield: 5 percent
Dunkirk: 5 percent
Hartland: 5 percent
Howard: 5 percent
Unnamed: 5 percent

The moderately well drained Deerfield, Dunkirk, Hartland, and Howard soils may be included in areas of this map unit. Also included are small areas of moderately well drained silty soils. Deerfield soils occupy slightly lower positions. Dunkirk, Hartland, and Howard soils occupy similar positions, but Dunkirk soils are silty and clayey; Hartland soils are silty; and Howard soils are loamy and gravelly. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

33 to 65 inches: rapid (6 to 20 inches/hour)
65 to 72 inches: rapid (6 to 20 inches/hour)

Colonie, calcareous substratum
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: low
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
0 to 9 inches: very strongly acid to neutral (4.5 to 7.3)
9 to 14 inches: very strongly acid to neutral (4.5 to 7.3)
14 to 25 inches: very strongly acid to neutral (4.5 to 7.3)
25 to 37 inches: very strongly acid to neutral (4.5 to 7.3)
37 to 49 inches: very strongly acid to neutral (4.5 to 7.3)
49 to 56 inches: strongly acid to moderately alkaline (5.1 to 8.4)
56 to 61 inches: strongly acid to moderately alkaline (5.1 to 8.4)
61 to 72 inches: strongly acid to moderately alkaline (5.1 to 8.4)
Permeability:
0 to 9 inches: moderately rapid or rapid (2 to 20 inches/hour)
9 to 14 inches: moderately rapid or rapid (2 to 20 inches/hour)
14 to 25 inches: moderately rapid or rapid (2 to 20 inches/hour)
25 to 37 inches: moderately rapid or rapid (2 to 20 inches/hour)
37 to 49 inches: moderately rapid or rapid (2 to 20 inches/hour)
49 to 56 inches: moderately rapid or rapid (2 to 20 inches/hour)
56 to 61 inches: moderately rapid or rapid (2 to 20 inches/hour)
61 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table in some areas of this map unit may severely limit the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of this map unit may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table in some areas of this map unit may impede excavation and grading and reduce the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

FcD—Factoryville-Colonie complex, 15 to 25 percent slopes

Setting

These soils are sandy, very deep, moderately steep, and well drained to somewhat excessively drained. They are on backslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 75 acres in size.

Map Unit Composition

Major Components
Factoryville: 45 percent
Colonie, calcareous substratum: 30 percent

56 to 61 inches: moderately rapid or rapid (2 to 20 inches/hour)
61 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.

- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table in some areas of this map unit may severely limit the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of this map unit may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table in some areas of this map unit may impede excavation and grading and reduce the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

FdF—Factoryville-Dunkirk complex, 25 to 60 percent slopes

Setting

These soils are sandy, and silty and clayey, very deep, steep, and well drained. They are on backslopes of proglacial deltas in the Champlain Valley. Areas range from 5 to 640 acres in size.

Map Unit Composition

Major Components
Factoryville: 45 percent
Dunkirk: 30 percent

Inclusions
Colonie: 8 percent
Hartland: 7 percent
Howard: 4 percent
Pittsfield: 4 percent
Unnamed: 2 percent

The somewhat excessively drained Colonie, Hartland, Howard, and Pittsfield soils may be included in areas of this map unit. Also included are small areas of moderately well drained silty soils. Colonie, Hartland, Howard, and Pittsfield soils occupy similar positions, but Hartland soils are silty; Howard soils are loamy and gravelly; and Pittsfield soils are loamy. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Shrink-swell potential: moderate
Surface runoff potential: high
Landform: lake plains
Parent material: silty glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
- 0 to 6 inches: strongly acid to slightly acid (5.1 to 6.5)
- 6 to 10 inches: strongly acid to neutral (5.1 to 7.3)
- 10 to 15 inches: strongly acid to neutral (5.1 to 7.3)
- 15 to 21 inches: strongly acid to neutral (5.1 to 7.3)
- 21 to 29 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 29 to 35 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 35 to 42 inches: slightly acid to moderately alkaline (6.1 to 8.4)
- 42 to 72 inches: slightly acid to moderately alkaline (6.1 to 8.4)

Permeability:
- 0 to 6 inches: moderate (0.6 to 2 inches/hour)
- 6 to 10 inches: moderate (0.6 to 2 inches/hour)
- 10 to 15 inches: moderate (0.6 to 2 inches/hour)
- 15 to 21 inches: moderate (0.6 to 2 inches/hour)
- 21 to 29 inches: slow to moderate (0.06 to 2 inches/hour)
- 29 to 35 inches: slow to moderate (0.06 to 2 inches/hour)
- 35 to 42 inches: slow to moderate (0.06 to 2 inches/hour)
- 42 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table in some areas severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The potential for shrink-swell in these soils results in a limited capacity to support a load without movement and may cause shifting foundations and cracking of basement walls and floors.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of this map unit may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through some areas of these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table in some areas impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling in some areas can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- The low bearing strength of these soils in some areas is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

FgB—Farmington-Galway complex, 3 to 15 percent slopes, very rocky, very stony

Setting

These soils are loamy, shallow and moderately deep, gently sloping to strongly sloping, and well drained. They are on summits and shoulders of glaciated hills in the Champlain Valley. Areas range from 3 to 185 acres in size.

Map Unit Composition

Major Components
Farmington, very rocky, very stony: 45 percent
Galway, very rocky, very stony: 30 percent

Inclusions
Nellis: 5 percent
Rock Outcrop: 5 percent
Amenia: 4 percent
Elmridge: 4 percent
Massena: 4 percent
Unnamed: 3 percent

The Nellis, moderately well drained Amenia and Elmridge, and somewhat poorly drained Massena soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Nellis soils occupy similar positions, but are very deep. Amenia and Elmridge soils occupy slightly lower positions, are both very deep, and Elmridge soils are loamy over clayey. Massena soils are on small depressions and drainageways and are very deep. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Drainage class: well drained

Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy till derived from limestone
Reaction (pH):
- 0 to 5 inches: moderately acid to neutral (5.6 to 7.3)
- 5 to 9 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 9 to 18 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 18 to 35 inches: slightly alkaline or moderately alkaline (7.4 to 8.4)
- 35 inches, bedrock

Permeability:
- 0 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 to 35 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 35 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops (fig. 19).

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep and shallow soils.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

Figure 19.—An area of Farmington-Galway complex at the Fort Crown Point state historic site. This photo illustrates depth to limestone bedrock in these map units. The rock outcrops and surface stoniness make tillage impractical; however, these areas could provide marginal pasture. This map unit has severe limitations for residential development and local roads and streets because of the mostly shallow depth to bedrock.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

FkF—Farmington-Rock outcrop complex, 35 to 60 percent slopes, very stony

Setting

This map unit consists of areas of exposed bedrock and soils that are loamy, shallow, very steep, and well drained. It is on backslopes of glaciated hills in the Champlain Valley. Areas range from 5 to 35 acres in size.

Map Unit Composition

Major Components
Farmington, very stony: 60 percent
Rock outcrop, very stony: 30 percent

Inclusions
Galway: 4 percent
Nellis: 3 percent
Unnamed: 3 percent

The Galway and Nellis soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Galway and Nellis soils occupy similar positions, but Galway soils are moderately deep to bedrock; and Nellis soils are very deep. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Farmington, very stony: no

Hydrologic group:
  Farmington, very stony: D
  Rock outcrop, very stony: unranked

Soil Properties and Qualities

Farmington, very stony
Drainage class: well drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy till derived from limestone

Reaction (pH):
- 0 to 6 inches: strongly acid to neutral (5.1 to 7.3)
- 6 to 13 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 13 inches, bedrock

Permeability:
- 0 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 6 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 13 inches, bedrock

Rock outcrop, very stony

Characteristics not defined for this component.

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture

- These soils are generally not recommended for pasture.

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems are advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

FnB—Fernlake loamy fine sand, 3 to 8 percent slopes, very bouldery

Setting

This soil is sandy, very deep, gently sloping, and somewhat excessively drained. It is on summits and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 380 acres in size.

Map Unit Composition

Major Components
Fernlake, very bouldery: 85 percent

Inclusions
Champlain: 3 percent
Hermon: 3 percent
Monadnock: 3 percent
Becket: 2 percent
Adams: 1 percent
Colton: 1 percent
Sunapee: 1 percent
Unnamed: 1 percent

The Champlain, Hermon, Adams, well drained Monadnock and Becket, excessively drained Colton, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Champlain, Hermon, Adams, Monadnock, Becket, and Colton soils occupy similar positions, but Champlain and Adams soils have few or no rock fragments and Champlain soils lack a spodic horizon; Monadnock and Becket soils are loamy; and Hermon and Colton soils

are sandy and gravelly. Sunapee soils occupy slightly lower positions, and are loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
Fernlake, very bouldery: no
Hydrologic group:
Fernlake, very bouldery: A

Soil Properties and Qualities

Fernlake, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: sandy ablation till derived from gneiss
Reaction (pH):
0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
4 to 8 inches: extremely acid to strongly acid (3.5 to 5.5)
8 to 19 inches: very strongly acid to moderately acid (4.5 to 6.0)
19 to 33 inches: very strongly acid to moderately acid (4.5 to 6.0)
33 to 41 inches: strongly acid to slightly acid (5.1 to 6.5)
41 to 57 inches: strongly acid to slightly acid (5.1 to 6.5)
57 to 72 inches: strongly acid to slightly acid (5.1 to 6.5)
Permeability:
0 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
2 to 4 inches: moderately rapid or rapid (2 to 20 inches/hour)
4 to 8 inches: moderately rapid or rapid (2 to 20 inches/hour)
8 to 19 inches: moderately rapid or rapid (2 to 20 inches/hour)
19 to 33 inches: moderately rapid or rapid (2 to 20 inches/hour)
33 to 41 inches: moderately rapid to very rapid (2 to 100 inches/hour)
41 to 57 inches: moderately rapid to very rapid (2 to 100 inches/hour)
57 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Poorly treated effluent may pollute the water table.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

FnC—Fernlake loamy fine sand, 8 to 15 percent slopes, very bouldery

Setting

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Poorly treated effluent may pollute the water table.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

FrB—Factoryville loamy fine sand, 2 to 8 percent slopes

Setting

This soil is sandy, very deep, gently sloping, and well drained. It is on summits and shoulders of proglacial deltas in the Champlain Valley. Areas range from 3 to 95 acres in size.

Map Unit Composition

Major Components
Factoryville: 85 percent

Inclusions
Deerfield: 5 percent
Unnamed: 3 percent
Windsor: 3 percent
Claverack: 1 percent
Dunkirk: 1 percent
Hartland: 1 percent
Stafford: 1 percent

The moderately well drained Deerfield and Claverack, excessively drained Windsor, Dunkirk, Hartland, and somewhat poorly drained Stafford soils may be included in areas of this map unit. Also included are small areas of moderately well drained silty

soils. Deerfield and Claverack soils occupy slightly lower positions, and Claverack soils are sandy over clayey. Windsor, Dunkirk, and Hartland soils occupy similar positions, but Windsor soils have coarser sands; Dunkirk soils are silty and clayey; and Hartland soils are silty. Stafford soils are on small depressions and drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2s
Hydric soil rating:
  Factoryville: no
Hydrologic group:
  Factoryville: A

Soil Properties and Qualities

Factoryville
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 24 to 39 inches
  Water table kind: apparent
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 11 inches: moderately acid to neutral (5.6 to 7.3)
  11 to 19 inches: strongly acid to neutral (5.1 to 7.3)
  19 to 29 inches: strongly acid to neutral (5.1 to 7.3)
  29 to 33 inches: strongly acid to neutral (5.1 to 7.3)
  33 to 65 inches: moderately acid to neutral (5.6 to 7.3)
  65 to 72 inches: moderately acid to neutral (5.6 to 7.3)
Permeability:
  0 to 11 inches: rapid (6 to 20 inches/hour)
  11 to 19 inches: rapid (6 to 20 inches/hour)
  19 to 29 inches: rapid (6 to 20 inches/hour)
  29 to 33 inches: rapid (6 to 20 inches/hour)
  33 to 65 inches: rapid (6 to 20 inches/hour)
  65 to 72 inches: rapid (6 to 20 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table in some areas severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table in some areas impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

FuA—Fluvaquents-Udifluvents complex, frequently flooded, nearly level

Setting

These soils are loamy, sandy, or gravelly, very deep, and somewhat poorly drained to very poorly drained, or excessively drained to moderately well drained. It is on flood plains throughout the county. Areas range from 3 to 510 acres in size.

Map Unit Composition

Major Components
Fluvaquents, frequently flooded: 45 percent
Udifluvents, frequently flooded: 30 percent

Inclusions
Rippowam: 5 percent
Rumney: 5 percent

Cornish: 3 percent
Podunk: 3 percent
Pootatuck: 3 percent
Lovewell: 2 percent
Occum: 2 percent
Ondawa: 2 percent

The poorly drained Rippowam and Rumney, somewhat poorly drained Cornish, moderately well drained Podunk, Pootatuck, and Lovewell, and well drained Occum and Ondawa soils may be included in areas of this map unit. Rippowam and Rumney soils occupy lower positions than Fluvaquents soils and are loamy. Cornish soils occupy similar positions as Fluvaquents soils and are silty. Podunk, Pootatuck, and Lovewell soils occupy slightly lower positions than Udifluvents soils, Podunk and Pootatuck soils are loamy, and Lovewell soils are silty. Occum and Ondawa soils occupy similar positions as Udifluvents soils and are loamy. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w

28 to 34 inches: moderate to very rapid (0.6 to 100 inches/hour)
34 to 38 inches: moderate to very rapid (0.6 to 100 inches/hour)
38 to 44 inches: moderate to very rapid (0.6 to 100 inches/hour)
44 to 56 inches: moderate to very rapid (0.6 to 100 inches/hour)
56 to 72 inches: moderate to very rapid (0.6 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to use as cropland because of frequent flooding.

Pasture
- These soils are generally unsuited to use as pasture because of frequent flooding.

Woodland
- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to

them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by ponding or flooding. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: Included in the FuA map unit are some areas of frigid soils. This should not affect use and management of this map unit.

GeB—Georgia loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on summits and shoulders of glaciated hills and till plains in the Champlain Valley. Areas range from 3 to 220 acres in size.

Map Unit Composition

Major Components
Georgia: 85 percent

Inclusions
Massena: 5 percent
Pittsfield: 3 percent
Amenia: 2 percent
Bombay: 2 percent
Cayuga: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Massena, well drained Pittsfield, Amenia, Bombay, and Cayuga soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Massena soils are on small depressions and drainageways. Pittsfield soils occupy higher positions. Amenia, Bombay, and Cayuga soils occupy similar positions, but Amenia soils have a higher pH, Bombay soils have a slightly higher clay content in the subsoil, and Cayuga soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland

  15 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  20 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  30 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland

- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

GeC—Georgia loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and moderately well drained. It is on shoulders and backslopes of glaciated hills and till plains in the Champlain Valley. Areas range from 3 to 50 acres in size.

Map Unit Composition

Major Components
Georgia: 85 percent

Inclusions
Massena: 5 percent
Pittsfield: 3 percent
Amenia: 2 percent
Bombay: 2 percent
Cayuga: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Massena, well drained Pittsfield, Amenia, Bombay, and Cayuga soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Massena soils are on small depressions and drainageways. Pittsfield soils occupy higher positions. Amenia, Bombay, and Cayuga soils occupy similar positions, but Amenia soils have a higher pH; Bombay soils have a slightly higher clay content in the subsoil; and Cayuga soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

 30 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations due to seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

GoA—Gougeville mucky loamy fine sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and poorly drained. It is on toeslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 85 acres in size.

Map Unit Composition

Major Components
Gougeville: 85 percent

Inclusions
Stafford: 5 percent
Unnamed: 4 percent
Cosad: 3 percent
Whallonsburg: 2 percent
Sun: 1 percent

The somewhat poorly drained Stafford and Cosad, very poorly drained Whallonsburg, and Sun soils are included in areas of this map unit. Also included are areas of very poorly drained sandy soils. Stafford and Cosad soils occupy higher positions, and Cosad soils are sandy over clayey. Whallonsburg soils occupy slightly lower positions, and are mucky over clayey. Sun soils occupy similar positions, but are loamy and are underlain by till. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

    58 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops caused by the seasonal high water table.

Pasture
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained and very poorly drained soils should be avoided when locating log landings.

- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

HaB—Hailesboro very fine sandy loam, 3 to 8 percent slopes

Setting

This soil is silty and clayey, very deep, gently sloping, and somewhat poorly drained. It is on footslopes of glacial-valley walls in the Adirondack Upland. Areas range from 3 to 65 acres in size.

Map Unit Composition

Major Components

Hailesboro: 85 percent

Inclusions
Depeyster: 5 percent
Roundabout: 4 percent
Wegatchie: 3 percent
Naumburg: 2 percent
Unnamed: 1 percent

The moderately well drained Depeyster, Roundabout, Naumburg, and poorly drained Wegatchie soils may be included in areas of this map unit. Also included are areas of somewhat poorly drained sandy over clayey soils. Depeyster soils occupy higher positions. Wegatchie soils occupy lower positions. Roundabout and Naumburg soils occupy similar positions, but Roundabout soils are silty; and Naumburg soils are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Soil Properties and Qualities

Hailesboro
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: moderate
Surface runoff potential: very high
Landform: glacial-valley walls
Parent material: silty glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 1 inch: extremely acid to slightly acid (4.0 to 6.5)
  1 to 9 inches: moderately acid to neutral (5.6 to 7.3)
  9 to 17 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  17 to 23 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  23 to 30 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  30 to 44 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  44 to 54 inches: neutral to moderately alkaline (6.6 to 8.4)
  54 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 9 inches: moderate (0.6 to 2 inches/hour)
  9 to 17 inches: moderate (0.6 to 2 inches/hour)
  17 to 23 inches: moderate (0.6 to 2 inches/hour)
  23 to 30 inches: slow to moderate (0.06 to 2 inches/hour)
  30 to 44 inches: slow to moderate (0.06 to 2 inches/hour)
  44 to 54 inches: slow to moderate (0.06 to 2 inches/hour)
  54 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland

- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when

excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

HcB—Howard very cobbly loam, 2 to 8 percent slopes

Setting

These soils are loamy and gravelly, very deep, gently sloping, and well drained. They are on summits and shoulders of kame terraces and outwash terraces in the Champlain Valley. Areas range from 4 to 80 acres in size.

Map Unit Composition

Major Components
Howard: 85 percent

Inclusions
Colonie: 5 percent
Nellis: 4 percent
Chatfield: 2 percent
Pittsfield: 2 percent
Factoryville: 1 percent
Unnamed: 1 percent

The somewhat excessively drained Colonie, Nellis, Chatfield, Pittsfield, and Factoryville soils may be included in areas of this map unit. Also included are areas that have an extremely cobbly surface. Colonie, Nellis, Chatfield, Pittsfield, and Factoryville soils occupy similar positions, but Colonie and Factoryville soils are sandy; Nellis, Chatfield, and Pittsfield soils are loamy; and Chatfield soils are moderately deep to bedrock. Included areas can occupy about 15 percent of this unit.

  15 to 22 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  22 to 35 inches: very rapid (20 to 100 inches/hour)
  35 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- Many large rock fragments in these soils impede workability with heavy equipment during the construction of dwellings with basements. Relocation or removal of rock fragments may significantly increase construction costs.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Many large stones in these soils impede workability with heavy equipment during installation. Relocation or removal of large stones can significantly increase the cost of the system.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

HcC—Howard very cobbly loam, 8 to 15 percent slopes

Setting

These soils are loamy and gravelly, very deep, strongly sloping, and well drained. They are on backslopes of kame terraces and outwash terraces in the Champlain Valley. Areas range from 5 to 85 acres in size

Map Unit Composition

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.
- Many large rock fragments in these soils impede workability with heavy equipment during the construction of dwellings with basements. Relocation or removal of rock fragments may significantly increase construction costs.

Septic Tank Absorption Fields

- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Many large stones in these soils impede workability with heavy equipment during installation. Relocation or removal of large stones can significantly increase the cost of the system.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

HcD—Howard very cobbly loam, 15 to 25 percent slopes

Setting

These soils are loamy and gravelly, very deep, moderately steep, and well drained. They are on backslopes of kame terraces and outwash terraces in the Champlain Valley. Areas range from 5 to 140 acres in size

Map Unit Composition

  22 to 35 inches: very rapid (20 to 100 inches/hour)
  35 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.

- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.
- Many large rock fragments in these soils impede workability with heavy equipment during the construction of dwellings with basements. Relocation or removal of rock fragments may significantly increase construction costs.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Many large stones in these soils impede workability with heavy equipment during installation. Relocation or removal of large stones can significantly increase the cost of the system.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

HdB—Hartland very fine sandy loam, 2 to 8 percent slopes

Setting

These soils are silty, very deep, gently sloping, and well drained. They are on summits and shoulders of lake plains in the Champlain Valley. Areas range from 3 to 65 acres in size.

Map Unit Composition

Major Components
Hartland: 85 percent

Inclusions
Dunkirk: 5 percent
Collamer: 4 percent
Factoryville: 3 percent
Colonie: 2 percent
Unnamed: 1 percent

The Dunkirk, Factoryville, somewhat excessively drained Colonie, and moderately well drained Collamer soils may be included in areas of this map unit. Also included are small areas of moderately well drained silty soils. Dunkirk, Factoryville, and Colonie soils occupy similar positions, but Dunkirk soils are silty and clayey; and Factoryville and Colonie soils are sandy. Collamer soils occupy slightly lower positions, and are silty and clayey. Included areas can occupy about 15 percent of this unit.

Cayuga: 2 percent
Unnamed: 1 percent

The somewhat excessively drained Colonie, Nellis, and moderately well drained Bombay and Cayuga soils may be included in areas of this map unit. Also included are areas that have an extremely cobbly surface. Colonie and Nellis soils occupy similar positions, but Colonie soils are sandy, and Nellis soils are loamy. Bombay and Cayuga soils occupy slightly lower positions, Bombay soils are loamy, and Cayuga soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3s
Hydric soil rating:
  Howard: no
Hydrologic group:
  Howard: A

Soil Properties and Qualities

Howard
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Landform: beach ridges
Parent material: gravelly outwash derived from limestone over loamy lodgment till derived from limestone
Reaction (pH):
  0 to 1 inch: extremely acid to slightly acid (4.0 to 6.5)
  1 to 6 inches: strongly acid to neutral (5.1 to 7.3)
  6 to 10 inches: strongly acid to neutral (5.1 to 7.3)
  10 to 13 inches: strongly acid to neutral (5.1 to 7.3)
  13 to 20 inches: strongly acid to neutral (5.1 to 7.3)
  20 to 29 inches: strongly acid to neutral (5.1 to 7.3)
  29 to 33 inches: strongly acid to neutral (5.1 to 7.3)
  33 to 54 inches: neutral to moderately alkaline (6.6 to 8.4)
  54 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
  0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
  1 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  6 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  10 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  13 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  20 to 29 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  29 to 33 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  33 to 54 inches: very rapid (20 to 100 inches/hour)
  54 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The HlB, HlC, and HmB map units have textures below 40 inches that are finer than typical for the range of the Howard series. This should not significantly affect use and management on a local basis for most purposes.

HlC—Howard very cobbly fine sandy loam, 8 to 15 percent slopes, loamy substratum

Setting

These soils are loamy and gravelly, very deep, strongly sloping, and well drained. They are on backslopes of beach ridges in the Champlain Valley. Areas range from 3 to 130 acres in size.

Map Unit Composition

Major Components
Howard: 85 percent

Inclusions
Colonie: 5 percent
Nellis: 4 percent
Bombay: 3 percent
Cayuga: 2 percent
Unnamed: 1 percent

The somewhat excessively drained Colonie, Nellis, and moderately well drained Bombay and Cayuga soils may be included in areas of this map unit. Also included are areas that have an extremely cobbly surface. Colonie and Nellis soils occupy similar positions, but Colonie soils are sandy; and Nellis soils are loamy. Bombay and Cayuga soils occupy slightly lower positions; Bombay soils are loamy; and Cayuga soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

33 to 54 inches: very rapid (20 to 100 inches/hour)
54 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- Erosion control is needed when pastures are renovated.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

Correlation Note: The HlB, HlC, and HmB map units have textures below 40 inches that are finer than typical for the range of the Howard series. This should not significantly affect use and management on a local basis for most purposes.

HmB—Howard gravelly fine sandy loam, 2 to 8 percent slopes, loamy substratum

Setting

These soils are loamy and gravelly, very deep, gently sloping, and well drained. They are on summits and shoulders of beach ridges in the Champlain Valley. Areas range from 5 to 105 acres in size.

Map Unit Composition

Major Components
Howard: 85 percent

Inclusions
Colonie: 5 percent
Nellis: 4 percent
Bombay: 3 percent
Cayuga: 2 percent
Unnamed: 1 percent

The somewhat excessively drained Colonie, Nellis, and moderately well drained Bombay and Cayuga soils may be included in areas of this map unit. Also included are areas that have an extremely cobbly surface. Colonie and Nellis soils occupy similar positions, but Colonie soils are sandy; and Nellis soils are loamy. Bombay and Cayuga soils occupy slightly lower positions, Bombay soils are loamy, and Cayuga soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Correlation Note: The HlB, HlC, and HmB map units have textures below 40 inches that are finer than typical for the range of the Howard series. This should not significantly affect use and management on a local basis for most purposes.

HnC—Hermon gravelly loamy sand, 8 to 15 percent slopes, very bouldery

Setting

This soil is sandy and gravelly, very deep, strongly sloping, and somewhat excessively drained. It is on summits, shoulders, backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 5 to 65 acres in size.

Map Unit Composition

Major Components

Hermon, very bouldery: 85 percent

Inclusions

Monadnock: 5 percent
Fernlake: 4 percent
Colton: 3 percent
Becket: 2 percent
Sunapee: 1 percent

The well drained Monadnock and Becket, Fernlake, excessively drained Colton, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Monadnock, Becket, Fernlake, and Colton soils occupy similar positions, but Monadnock and Becket soils are loamy; Fernlake soils have less rock fragments; and Colton soils formed in outwash. Sunapee soils occupy slightly lower positions, and are loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
5 to 10 inches: moderately rapid or rapid (2 to 20 inches/hour)
10 to 20 inches: moderately rapid or rapid (2 to 20 inches/hour)
20 to 29 inches: very rapid (20 to 100 inches/hour)
29 to 38 inches: very rapid (20 to 100 inches/hour)
38 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations due to very bouldery or extremely stony surface conditions.

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

HnD—Hermon gravelly loamy sand, 15 to 35 percent slopes, very bouldery

Setting

This soil is sandy and gravelly, very deep, moderately steep and steep, and somewhat excessively drained. It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 135 acres in size.

Map Unit Composition

Major Components
Hermon, very bouldery: 85 percent

Inclusions
Monadnock: 5 percent
Fernlake: 4 percent
Colton: 3 percent

Becket: 2 percent
Adams: 1 percent

The well drained Monadnock and Becket, Fernlake, Adams, and excessively drained Colton soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Monadnock, Becket, Fernlake, Adams, and Colton soils occupy similar positions, but Monadnock and Becket soils are loamy, Fernlake soils have less rock fragments, Colton and Adams soils formed in outwash, and Adams soils have little or no rock fragments. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s

Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
  3 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
  5 to 10 inches: extremely acid to moderately acid (3.5 to 6.0)
  10 to 20 inches: extremely acid to moderately acid (3.5 to 6.0)
  20 to 29 inches: strongly acid or moderately acid (5.1 to 6.0)
  29 to 38 inches: strongly acid or moderately acid (5.1 to 6.0)
  38 to 72 inches: strongly acid or moderately acid (5.1 to 6.0)
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderately rapid or rapid (2 to 20 inches/hour)
  5 to 10 inches: moderately rapid or rapid (2 to 20 inches/hour)
  10 to 20 inches: moderately rapid or rapid (2 to 20 inches/hour)
  20 to 29 inches: very rapid (20 to 100 inches/hour)
  29 to 38 inches: very rapid (20 to 100 inches/hour)
  38 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture

- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and re-seeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

HrF—Hogback-Knob Lock complex, 35 to 60 percent slopes, very rocky, very bouldery

Setting

These soils are loamy and organic, shallow to very shallow, very steep, and well drained to excessively drained. They are on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 5 to 255 acres in size.

Map Unit Composition

Major Components
Hogback, very rocky, very bouldery: 45 percent
Knob Lock, very rocky, very bouldery: 30 percent

Inclusions
Rock outcrop: 9 percent
Rawsonville: 6 percent
Lyman: 4 percent
Mundalite: 3 percent
Unnamed: 3 percent

The Rawsonville, Lyman, and Mundalite soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Rawsonville, Lyman, and Mundalite soils occupy similar positions, but Rawsonville soils are moderately deep to bedrock; Lyman soils have less organic matter; and Mundalite soils are very deep to bedrock. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Hogback, very rocky, very bouldery: no
  Knob Lock, very rocky, very bouldery: no
Hydrologic group:
  Hogback, very rocky, very bouldery: D
  Knob Lock, very rocky, very bouldery: D

Soil Properties and Qualities

Hogback, very rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss

Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
3 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
4 to 6 inches: extremely acid to strongly acid (3.5 to 5.5)
6 to 14 inches: extremely acid to strongly acid (3.5 to 5.5)
14 inches, bedrock
Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
6 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 inches, bedrock

Knob Lock, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 1 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: non-saturated organic material over loamy till derived from gneiss
Reaction (pH):
0 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
3 to 7 inches: ultra acid or extremely acid (1.8 to 4.4)
7 to 9 inches: extremely acid or very strongly acid (3.5 to 5.0)
9 inches, bedrock
Permeability:
0 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
3 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
7 to 9 inches: moderate to very rapid (0.6 to 100 inches/hour)
9 inches, bedrock

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture

- These soils are generally not recommended for pasture.

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.

- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

HsD—Hollis-Rock outcrop complex, 15 to 35 percent slopes, very stony

Setting

This map unit consists of areas of exposed bedrock and soils that are loamy, shallow, moderately steep and steep, and well drained. It is on backslopes of glaciated hills in the Champlain Valley. Areas range from 3 to 95 acres in size.

Map Unit Composition

Major Components
Hollis, very stony: 45 percent
Rock outcrop, very stony: 30 percent

Inclusions
Chatfield: 9 percent
Unnamed: 7 percent
Charlton: 4 percent
Pittsfield: 3 percent
Cayuga: 2 percent

The Chatfield, Charlton, Pittsfield, and moderately well drained Cayuga soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Chatfield, Charlton and Pittsfield soils occupy similar positions, but Chatfield soils are moderately deep to bedrock; Charlton and Pittsfield soils are very deep; and Pittsfield soils have a higher pH. Cayuga soils are on benches or drainageways, are very deep, and are clayey over loamy. Included areas make up about 25 percent of this unit.

Interpretive Groups

Soil Properties and Qualities

Hollis, very stony
Drainage class: well drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 6 inches: very strongly acid to moderately acid (4.5 to 6.0)

6 to 13 inches: very strongly acid to moderately acid (4.5 to 6.0)
13 inches, bedrock

Permeability:
0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
6 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 inches, bedrock

Rock outcrop, very stony

Characteristics not defined for this component.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture
- The slope may restrict the use of most farm equipment.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

HsF—Hollis-Rock outcrop complex, 35 to 60 percent slopes, very stony

Setting

This map unit consists of areas of exposed bedrock and soils that are loamy, shallow, very steep, and well drained. It is on backslopes of glaciated hills in the Champlain Valley. Areas range from 5 to 480 acres in size.

Map Unit Composition

Characteristics not defined for this component.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.

- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

KaB—Kalurah silt loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on footslopes and backslopes of till plains and glaciated hills in the Adirondack Upland. Areas range from 3 to 540 acres in size.

Map Unit Composition

Major Components
Kalurah: 85 percent

Inclusions
Malone: 5 percent
Pyrites: 4 percent
Skerry: 3 percent
Nehasne: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Malone, well drained Pyrites and Nehasne, and Skerry soils may be included in areas of this map unit. Also included are areas with a very stony surface. Malone soils occupy slightly lower positions. Pyrites and Nehasne soils occupy higher positions, and Nehasne soils are moderately deep to bedrock. Skerry soils occupy similar positions, but have a spodic horizon. Included areas can occupy about 15 percent of this unit.

  32 to 47 inches: slow to moderately rapid (0.06 to 6 inches/hour)
  47 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland

- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when

excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

KaC—Kalurah silt loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and moderately well drained. It is on backslopes of till plains and glaciated hills in the Adirondack Upland. Areas range from 3 to 123 acres in size.

Map Unit Composition

Major Components
Kalurah: 85 percent

Inclusions
Pyrites: 5 percent
Malone: 4 percent
Skerry: 3 percent
Nehasne: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Malone, well drained Pyrites and Nehasne, and Skerry soils may be included in areas of this map unit. Also included are areas with a very stony surface. Malone soils occupy slightly lower positions. Pyrites and Nehasne soils occupy higher positions, and Nehasne soils are moderately deep to bedrock. Skerry soils occupy similar positions, but have a spodic horizon. Included areas can occupy about 15 percent of this unit.

  47 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

Surface fragment cover: very stony
Landform: glaciated hills, glaciated till plains
Parent material: loamy lodgment till derived from igneous and sedimentary rock
Reaction (pH):
 0 to 9 inches: moderately acid to neutral (5.6 to 7.3)
 9 to 13 inches: slightly acid or neutral (6.1 to 7.3)
 13 to 22 inches: slightly acid or neutral (6.1 to 7.3)
 22 to 32 inches: slightly acid or neutral (6.1 to 7.3)
 32 to 47 inches: neutral to moderately alkaline (6.6 to 8.4)
 47 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
 0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 13 to 22 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 22 to 32 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 32 to 47 inches: slow to moderately rapid (0.06 to 6 inches/hour)
 47 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations due to seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability due to strongly sloping areas.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

KyA—Kingsbury silty clay loam, 0 to 3 percent slopes

Setting

This soil is clayey, very deep, nearly level, and somewhat poorly drained (fig. 20). It is on footslopes of lake plains in the Champlain Valley. Areas range from 3 to 1,340 acres in size.

Map Unit Composition

Major Components
Kingsbury: 85 percent

Inclusions
Covington: 4 percent
Churchville: 3 percent
Cosad: 3 percent

Figure 20.—This photo is a good example of a flat-lying lake plain with Kingsbury silty clay loam soils in the town of Crown Point. These soils have high native fertility but are very clayey, with greater than 60 percent clay in the subsoil, and often 40 to 50 percent clay in the surface. Tillage at the proper moisture content (neither too wet, nor too dry) is essential to maintain good soil structure. Compaction can be a severe problem on these soils. Many of these terraces may be marine (Champlain Sea era) in origin.

Vergennes: 2 percent
Livingston: 1 percent
Niagara: 1 percent
Unnamed: 1 percent

The poorly drained Covington, Churchville, Cosad, Niagara, moderately well drained Vergennes, and very poorly drained Livingston soils may be included in areas of this map unit. Also included are areas of somewhat poorly drained soils that have a slightly lower clay content. Covington and Livingston soils occupy lower positions. Churchville, Cosad, and Niagara soils occupy similar positions, but Churchville soils are clayey over loamy, Cosad soils are sandy over clayey, and Niagara soils are silty and clayey. Vergennes soils occupy higher positions. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3w

  Kingsbury: D

Soil Properties and Qualities

Kingsbury
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches

Depth to seasonal high water table: 6 to 18 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: very high
Surface runoff potential: very high
Landform: lake plains
Parent material: clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 9 inches: strongly acid to slightly alkaline (5.1 to 7.8)
  9 to 14 inches: strongly acid to slightly alkaline (5.1 to 7.8)
  14 to 21 inches: strongly acid to slightly alkaline (5.1 to 7.8)
  21 to 34 inches: moderately alkaline (7.9 to 8.4)
  34 to 65 inches: moderately alkaline (7.9 to 8.4)
  65 to 93 inches: moderately alkaline (7.9 to 8.4)
Permeability:
  0 to 9 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
  9 to 14 inches: very slow or slow (0.001 to 0.2 inches/hour)
  14 to 21 inches: very slow or slow (0.001 to 0.2 inches/hour)
  21 to 34 inches: very slow or slow (0.001 to 0.2 inches/hour)
  34 to 65 inches: impermeable or very slow (0 to 0.06 inches/hour)
  65 to 93 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

Cropland
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Limiting log landing and haul road construction and operation activities to dry or frozen ground conditions will help overcome limitations due to clayey soils.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.

- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

KyB—Kingsbury silty clay loam, 3 to 8 percent slopes

Setting

This soil is clayey, very deep, gently sloping, and somewhat poorly drained. It is on footslopes of lake plains in the Champlain Valley. Areas range from 3 to 230 acres in size.

Map Unit Composition

Major Components
Kingsbury: 85 percent

Inclusions
Vergennes: 4 percent
Churchville: 3 percent
Cosad: 3 percent
Covington: 2 percent

65 to 93 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

Cropland

- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Limiting log landing and haul road construction and operation activities to dry or frozen ground conditions will help overcome limitations caused by clayey soils.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.

- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

LnA—Livingston mucky silty clay loam, 0 to 3 percent slopes

Setting

This soil is clayey, very deep, nearly level, and very poorly drained. It is on toeslopes of lake plains in the Champlain Valley. Areas range from 3 to 235 acres in size.

Map Unit Composition

Major Components
Livingston: 85 percent

Inclusions
Covington: 7 percent
Whallonsburg: 5 percent
Kingsbury: 2 percent
Catden: 1 percent

The poorly drained Covington, Whallonsburg, Catden, and somewhat poorly drained Kingsbury soils may be included in areas of this map unit. Also included are areas of very poorly drained soils that have a slightly lower clay content. Covington and Kingsbury soils occupy higher positions. Whallonsburg and Catden soils occupy similar positions, but Whallonsburg soils are mucky over clayey, and Catden soils are very deep muck. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 4w
Hydric soil rating:
  Livingston: yes
Hydrologic group:
  Livingston: C/D

Soil Properties and Qualities

Livingston
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent

  9 to 21 inches: very slow or slow (0.001 to 0.2 inches/hour)
  21 to 35 inches: very slow or slow (0.001 to 0.2 inches/hour)
  35 to 46 inches: very slow or slow (0.001 to 0.2 inches/hour)
  46 to 56 inches: impermeable or very slow (0 to 0.06 inches/hour)
  56 to 72 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture caused by ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Limiting construction activities to dry or frozen ground conditions will help overcome construction limitations of haul roads caused by clayey soils.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness and clayey soils.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets
- These soils are very limited for local roads and streets caused by the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

LvA—Lovewell very fine sandy loam, 0 to 3 percent slopes

Setting

This soil is silty, very deep, nearly level, and moderately well drained. It is on flood plains in the Adirondack Upland. Areas range from 5 to 80 acres in size.

Map Unit Composition

Major Components
Lovewell: 85 percent

Inclusions
Fluvaquents-Udifluvents: 5 percent
Cornish: 3 percent
Adams: 2 percent
Colton: 2 percent
Medomak: 2 percent
Croghan: 1 percent

The somewhat poorly drained and well drained Fluvaquents-Udifluvents, somewhat poorly drained Cornish, somewhat excessively drained Adams, excessively drained Colton, very poorly drained Medomak, and moderately well drained Croghan soils may be included in areas of this map unit. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Cornish soils occupy slightly lower positions. Adams and Colton soils occupy higher positions, and are sandy and gravelly. Medomak soils are on small depressions. Croghan soils occupy similar positions, but are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2w
Hydric soil rating:
  Lovewell: no
Hydrologic group:
  Lovewell: B/D

Soil Properties and Qualities

Lovewell
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 36 inches
  Water table kind: apparent
Flooding: occasional
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low

Surface runoff potential: low
Landform: flood plains
Parent material: silty alluvium derived from gneiss
Reaction (pH):
    0 to 11 inches: very strongly acid to slightly acid (4.5 to 6.5)
    11 to 20 inches: very strongly acid to slightly acid (4.5 to 6.5)
    20 to 30 inches: very strongly acid to slightly acid (4.5 to 6.5)
    30 to 50 inches: very strongly acid to slightly acid (4.5 to 6.5)
    50 to 56 inches: very strongly acid to slightly acid (4.5 to 6.5)
    56 to 75 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:

    11 to 20 inches: moderate (0.6 to 2 inches/hour)
    20 to 30 inches: moderate (0.6 to 2 inches/hour)
    30 to 50 inches: moderate (0.6 to 2 inches/hour)
    50 to 56 inches: rapid (6 to 20 inches/hour)
    56 to 75 inches: rapid (6 to 20 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Flooding may delay planting or damage crops in some years.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.

- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

LyD—Lyman-Knob Lock complex, 15 to 35 percent slopes, very rocky, very bouldery

Setting

These soils are loamy and organic, shallow to very shallow, moderately steep and steep, and well drained to excessively drained. They are on backslopes of glaciated

hillsides or mountainsides in the Adirondack Upland. Areas range from 3 to 130 acres in size.

Map Unit Composition

Major Components
Lyman, very rocky, very bouldery: 45 percent
Knob Lock, very rocky, very bouldery: 30 percent

Inclusions
Tunbridge: 10 percent
Rock outcrop: 5 percent
Hogback: 3 percent
Becket: 2 percent
Hermon: 2 percent
Monadnock: 2 percent
Unnamed: 1 percent

The Tunbridge, Hogback, Becket, Monadnock, and Hermon soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Tunbridge, Hogback, Becket, Monadnock, and Hermon soils occupy similar positions, but Tunbridge soils are moderately deep to bedrock; Hogback soils have more organic matter than Lyman soils; Becket, Monadnock, and Hermon soils are very deep to bedrock; Monadnock soils are loamy over sandy or gravelly; and Hermon soils are sandy and gravelly. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
18 inches, bedrock

Knob Lock, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 1 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very high
Landform: glaciated hillside or mountainsides
Parent material: non-saturated organic material over loamy till derived from gneiss
Reaction (pH):
0 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
3 to 7 inches: ultra acid or extremely acid (1.8 to 4.4)
7 to 9 inches: extremely acid or very strongly acid (3.5 to 5.0)
9 inches, bedrock

Permeability:
0 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
3 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
7 to 9 inches: moderate to very rapid (0.6 to 100 inches/hour)
9 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture
- The slope may restrict the use of most farm equipment.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.

- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

LyF—Lyman-Knob Lock complex, 35 to 60 percent slopes, very rocky, very bouldery

Setting

These soils are loamy and organic, shallow to very shallow, very steep, and well drained to excessively drained. They are on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 3 to 340 acres in size.

Map Unit Composition

Major Components
Lyman, very rocky, very bouldery: 45 percent
Knob Lock, very rocky, very bouldery: 30 percent

Inclusions
Rock outcrop: 9 percent
Tunbridge: 6 percent
Hogback: 3 percent
Becket: 2 percent
Hermon: 2 percent
Monadnock: 2 percent
Unnamed: 1 percent

The Tunbridge, Hogback, Becket, Monadnock, and Hermon soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Tunbridge, Hogback, Becket, Monadnock, and Hermon soils occupy similar positions, but Tunbridge soils are moderately deep to bedrock; Hogback soils have more organic matter than Lyman soils; Becket, Monadnock, and Hermon soils are very deep to bedrock; Monadnock soils are loamy over sandy or gravelly; and Hermon soils are sandy and gravelly. - 9 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.

- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MaB—Malone silt loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and somewhat poorly drained. It is on footslopes and toeslopes of till plains and glaciated hills in the Adirondack Upland. Areas range from 3 to 115 acres in size.

Map Unit Composition

Major Components
Malone: 85 percent

Inclusions
Kalurah: 5 percent
Typic Endoaquolls: 4 percent
Adirondack: 3 percent
Nehasne: 2 percent
Unnamed: 1 percent

The moderately well drained Kalurah, poorly drained Typic Endoquolls, Adirondack, and well drained Nehasne soils may be included in areas of this map unit. Also included are areas with a very stony surface. Kalurah and Nehasne soils occupy higher positions, and Nehasne soils are moderately deep to bedrock. Typic Endoquolls soils occupy lower positions. Adirondack soils occupy similar positions, but have a spodic horizon. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
Malone: no
Hydrologic group:
Malone: B/D

Soil Properties and Qualities

Malone
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 18 to 38 inches to densic material
Depth to seasonal high water table: 6 to 18 inches
Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: glaciated till plains, glaciated hills
Parent material: loamy lodgment till derived from igneous and sedimentary rock
Reaction (pH):
0 to 7 inches: moderately acid or slightly acid (5.6 to 6.5)
7 to 12 inches: moderately acid to neutral (5.6 to 7.3)
12 to 17 inches: slightly acid or neutral (6.1 to 7.3)
17 to 25 inches: slightly acid or neutral (6.1 to 7.3)
25 to 72 inches: neutral or slightly alkaline (6.6 to 7.8)

Permeability:
- 0 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 12 to 17 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 17 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 25 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse-grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

MbB—Malone silt loam, 3 to 8 percent slopes, very stony

Setting

This soil is loamy, very deep, gently sloping, and somewhat poorly drained. It is on footslopes and toeslopes of till plains and glaciated hills in the Adirondack Upland. Areas range from 3 to 190 acres in size.

Map Unit Composition

Major Components

Malone, very stony: 85 percent

Inclusions

Kalurah: 5 percent
Typic Endoaquolls: 4 percent
Adirondack: 3 percent
Nehasne: 2 percent
Unnamed: 1 percent

The moderately well drained Kalurah, poorly drained Typic Endoquolls, somewhat poorly drained Adirondack, and well drained Nehasne soils may be included in areas of this map unit. Also included are areas with an extremely stony surface. Kalurah and Nehasne soils occupy higher positions, and Nehasne soils are moderately deep to bedrock. Typic Endoquolls soils occupy lower positions. Adirondack soils occupy similar

positions, but have a spodic horizon. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

  12 to 17 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  17 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  25 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

McA—Massena gravelly silt loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and somewhat poorly drained. It is on footslopes and toeslopes of till plains and drumlinoid ridges in the Champlain Valley. Areas range from 3 to 70 acres in size.

Map Unit Composition

Major Components
Massena: 85 percent

Inclusions
Amenia: 4 percent
Sun: 3 percent
Bombay: 2 percent
Churchville: 2 percent
Georgia: 2 percent
Unnamed: 2 percent

The moderately well drained Amenia, Bombay, and Georgia, poorly drained Sun, and somewhat poorly drained Churchville soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Amenia, Bombay, and Georgia soils occupy higher positions. Sun soils are on small depressions and drainageways. Churchville soils occupy similar positions, but are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained

9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
18 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
24 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland

- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture

- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

McB—Massena gravelly silt loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and somewhat poorly drained. It is on footslopes of till plains and drumlinoid ridges in the Champlain Valley. Areas range from 3 to 115 acres in size.

Map Unit Composition

Major Components
Massena: 85 percent

Inclusions
Amenia: 4 percent
Sun: 3 percent
Bombay: 2 percent
Churchville: 2 percent
Georgia: 2 percent
Unnamed: 2 percent

The moderately well drained Amenia, Bombay, and Georgia, poorly drained Sun, and somewhat poorly drained Churchville soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Amenia, Bombay, and Georgia soils occupy higher positions. Sun soils are on small depressions and drainageways. Churchville soils occupy similar positions, but are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
  Massena: no
Hydrologic group:
  Massena: A/D

Soil Properties and Qualities

Massena
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
    Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: till plains, drumlinoid ridges
Parent material: loamy lodgment till derived from limestone
Reaction (pH):
    0 to 9 inches: moderately acid to neutral (5.6 to 7.3)
    9 to 18 inches: moderately acid to neutral (5.6 to 7.3)
    18 to 24 inches: moderately acid to neutral (5.6 to 7.3)
    24 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
    0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    9 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    18 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    24 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.

- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

MdA—Medomak mucky silt loam, 0 to 3 percent slopes

Setting

This soil is silty, very deep, nearly level, and very poorly drained. It is on flood plains in the Adirondack Upland. Areas range from 5 to 115 acres in size.

Map Unit Composition

Major Components
Medomak: 85 percent

Inclusions
Charles: 5 percent
Burnt Vly: 3 percent
Cornish: 3 percent
Rumney: 3 percent
Fluvaquents-Udifluvents: 1 percent

The poorly drained Charles and Rumney, very poorly drained Burnt Vly, somewhat poorly drained Cornish, and somewhat poorly drained and well drained Fluvaquents-Udifluvents may be included in areas of this map unit. Charles and Rumney soils occupy slightly higher positions, and Rumney soils are loamy. Burnt Vly soils occupy similar positions, but are mucky over sandy. Cornish soils occupy higher positions. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
    Medomak: yes
Hydrologic group:
    Medomak: B/D

Soil Properties and Qualities

Medomak
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
    Water table kind: apparent
Flooding: frequent
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: flood plains
Parent material: silty alluvium derived from gneiss
Reaction (pH):
    0 to 1 inch: extremely acid to neutral (3.5 to 7.3)
    1 to 5 inches: extremely acid to neutral (3.5 to 7.3)
    5 to 11 inches: extremely acid to neutral (3.5 to 7.3)
    11 to 20 inches: extremely acid to neutral (3.5 to 7.3)
    20 to 29 inches: extremely acid to neutral (3.5 to 7.3)
    29 to 31 inches: extremely acid to slightly alkaline (3.5 to 7.8)
    31 to 41 inches: extremely acid to slightly alkaline (3.5 to 7.8)
    41 to 48 inches: extremely acid to slightly alkaline (3.5 to 7.8)
    48 to 72 inches: extremely acid to slightly alkaline (3.5 to 7.8)
Permeability:
    0 to 1 inch: moderately slow to rapid (0.2 to 20 inches/hour)
    1 to 5 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
    5 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    11 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    20 to 29 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    29 to 31 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

31 to 41 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
41 to 48 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
48 to 72 inches: moderate to rapid (0.6 to 20 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The MdA map unit is a taxadjunct to the Medomak series because the pedon qualifies as having a mollic epipedon in the Ap horizon and is a Mollisols. The classification of the taxadjunct is Coarse-silty, mixed, superactive, frigid Fluvaquentic Endoaquolls. The classification of the Medomak series is Coarse-silty, mixed, superactive, nonacid, frigid Fluvaquentic Humaquepts. This should not significantly affect use and management on a local basis for most purposes.

MhB—Monadnock fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy over sandy or gravelly, very deep, gently sloping, and well drained (fig. 21). It is on summits and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 330 acres in size.

Map Unit Composition

Major Components
Monadnock: 85 percent

Inclusions
Becket: 5 percent
Fernlake: 3 percent
Sunapee: 3 percent
Adams: 2 percent
Pyrities: 2 percent

The Becket, Pyrities, somewhat excessively drained Fernlake and Adams, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Becket, Pyrities, Fernlake, and Adams soils occupy similar positions, but Becket soils have a dense substratum; Pyrities soils lack a spodic horizon and have a higher pH; Fernlake soils are sandy; and Adams soils are sandy and have little or no rock fragments. Sunapee soils occupy slightly lower positions. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

 30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
 37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland

- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.

Figure 21.—This oblique aerial view shows the till plain south of Lake Placid Village where most of the seed potato farming in the county occurs. The majority of the cropland is in the non-bouldery phase of the Monadnock soils. Boulders and stones have been removed from the surface during clearing and over the years during tillage operations. These soils have low native fertility, but because of cool and acidic conditions, they are favorable for production of certified, rust-free, seed potatoes.

- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

MhC—Monadnock fine sandy loam, 8 to 15 percent slopes

Setting

This soil is loamy over sandy or gravelly, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 110 acres in size.

Map Unit Composition

Major Components
Monadnock: 85 percent

Inclusions
Becket: 5 percent
Fernlake: 3 percent
Sunapee: 3 percent
Adams: 2 percent
Pyrities: 2 percent

The Becket, Pyrities, somewhat excessively drained Fernlake and Adams, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Becket, Pyrities, Fernlake, and Adams soils occupy similar positions, but Becket soils have a dense substratum; Pyrities soils lack a spodic horizon and have a higher pH; Fernlake soils are sandy, and Adams soils are sandy and have little or no rock fragments. Sunapee soils occupy slightly lower positions. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

  12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.

- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

MkB—Monadnock fine sandy loam, 3 to 8 percent slopes, very bouldery

Setting

This soil is loamy over sandy or gravelly, very deep, gently sloping, and well drained. It is on summits and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 200 acres in size.

Map Unit Composition

Major Components
Monadnock, very bouldery: 85 percent

Inclusions
Becket: 5 percent
Fernlake: 3 percent
Sunapee: 3 percent
Adams: 2 percent
Pyrities: 2 percent

The Becket, Pyrities, somewhat excessively drained Fernlake and Adams, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Pyrities, Fernlake, and Adams soils occupy similar positions, but Becket soils have a dense substratum; Pyrities soils lack a spodic horizon and have a higher pH; Fernlake soils are sandy; and Adams soils are sandy and have little or no rock fragments. Sunapee soils occupy slightly lower positions. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s

Shrink-swell potential: low
Surface runoff potential: low
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till over sandy ablation till derived from gneiss
Reaction (pH):
    0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
    2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
    3 to 12 inches: extremely acid to moderately acid (3.5 to 6.0)
    12 to 19 inches: extremely acid to moderately acid (3.5 to 6.0)
    19 to 30 inches: extremely acid to moderately acid (3.5 to 6.0)
    30 to 37 inches: extremely acid to moderately acid (3.5 to 6.0)
    37 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)
Permeability:
    0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
    2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    3 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
    37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.

- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

MkC—Monadnock fine sandy loam, 8 to 15 percent slopes, very bouldery

Setting

This soil is loamy over sandy or gravelly, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 510 acres in size.

Map Unit Composition

    3 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
    37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

MkD—Monadnock fine sandy loam, 15 to 35 percent slopes, very bouldery

Setting

This soil is loamy over sandy or gravelly, very deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 185 acres in size.

Map Unit Composition

Major Components
Monadnock, very bouldery: 85 percent

Inclusions
Becket: 5 percent
Adams: 3 percent
Fernlake: 3 percent
Pyrities: 3 percent
Sunapee: 1 percent

The Becket, Pyrities, somewhat excessively drained Fernlake and Adams, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Pyrities, Fernlake, and Adams soils occupy similar positions, but Becket soils have a dense substratum; Pyrities soils lack a spodic horizon and have a higher pH; Fernlake soils are sandy; and Adams soils are sandy and have little or no rock fragments. Sunapee soils are on drainageways. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Soil Properties and Qualities

Monadnock, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till over sandy ablation till derived from gneiss

Reaction (pH):
- 0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
- 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
- 3 to 12 inches: extremely acid to moderately acid (3.5 to 6.0)
- 12 to 19 inches: extremely acid to moderately acid (3.5 to 6.0)
- 19 to 30 inches: extremely acid to moderately acid (3.5 to 6.0)
- 30 to 37 inches: extremely acid to moderately acid (3.5 to 6.0)
- 37 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)

Permeability:
- 0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MkF—Monadnock fine sandy loam, 35 to 60 percent slopes, very bouldery

Setting

This soil is loamy over sandy or gravelly, very deep, very steep, and well drained. It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 40 acres in size.

37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones, and the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.

- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MmF—Monadnock-Adams complex, 25 to 60 percent slopes, bouldery

Setting

These soils are loamy over sandy or gravelly, and sandy, very deep, very steep, and well drained. They are on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 5 to 325 acres in size.

Map Unit Composition

Major Components
Monadnock, very bouldery: 55 percent
Adams: 25 percent

Inclusions
Colton: 7 percent
Fernlake: 7 percent
Becket: 6 percent

The excessively drained Colton, Fernlake, and Becket soils may be included in areas of this map unit. Also included are areas that have a very bouldery surface. Colton, Fernlake, and Becket soils occupy similar positions, but Colton soils are sandy and gravelly; Fernlake soils are sandy till; and Becket soils have a dense substratum. Included areas can occupy about 20 percent of this unit.

- 14 to 23 inches: moderately rapid to very rapid (2 to 100 inches/hour)
- 23 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The excessive rate of fluid movement through these soils in some areas limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MnC—Monadnock-Tunbridge complex, 8 to 15 percent slopes, rocky, very bouldery

Setting

These soils are loamy over sandy and gravelly, and loamy, very deep and moderately deep, strongly sloping, and well drained. They are on backslopes and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 620 acres in size.

Map Unit Composition

Major Components
Monadnock, rocky, very bouldery: 45 percent
Tunbridge, rocky, very bouldery: 30 percent

Inclusions
Becket: 8 percent
Lyman: 7 percent
Sunapee: 5 percent
Knob Lock: 3 percent
Rock outcrop: 2 percent

The Becket, Lyman, Knob Lock, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Lyman, and Knob Lock soils occupy similar positions, but Becket soils have a dense substratum; Lyman soils are shallow to bedrock; and Knob Lock soils are shallow to very shallow to bedrock, and are organic. Sunapee soils occupy slightly

lower positions than Monadnock soils. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

 7 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 18 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 27 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

MnD—Monadnock-Tunbridge complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

These soils are loamy over sandy and gravelly, and loamy, very deep and moderately deep, moderately steep and steep, and well drained. They are on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 350 acres in size.

Knob Lock: 3 percent
Sunapee: 2 percent

The Becket, Lyman, Knob Lock, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Becket, Lyman, and Knob Lock soils occupy similar positions, but Becket soils have a dense substratum; Lyman soils are shallow to bedrock; and Knob Lock soils are shallow to very shallow to bedrock, and are organic. Sunapee soils are on drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Monadnock, rocky, very bouldery: no
  Tunbridge, rocky, very bouldery: no

  Monadnock, rocky, very bouldery: A
  Tunbridge, rocky, very bouldery: B

Soil Properties and Qualities

Monadnock, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate to high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till over sandy ablation till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
  3 to 12 inches: extremely acid to moderately acid (3.5 to 6.0)
  12 to 19 inches: extremely acid to moderately acid (3.5 to 6.0)
  19 to 30 inches: extremely acid to moderately acid (3.5 to 6.0)
  30 to 37 inches: extremely acid to moderately acid (3.5 to 6.0)
  37 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  30 to 37 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  37 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Tunbridge, rocky, very bouldery
Drainage class: well drained

Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
- 3 to 4 inches: extremely acid to moderately acid (3.5 to 6.0)
- 4 to 7 inches: extremely acid to moderately acid (3.5 to 6.0)
- 7 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
- 13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
- 18 to 27 inches: strongly acid to slightly acid (5.1 to 6.5)
- 27 inches, bedrock

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 4 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 27 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Locating haul roads on soils that are deeper to bedrock, or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations due to moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.

- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MnF—Monadnock-Tunbridge complex, 35 to 60 percent slopes, rocky, very bouldery

Setting

These soils are loamy over sandy and gravelly, and loamy, very deep and moderately deep, very steep, and well drained. They are on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 300 acres in size.

Map Unit Composition

Major Components
Monadnock, rocky, very bouldery: 45 percent
Tunbridge, rocky, very bouldery: 30 percent

Inclusions
Becket: 8 percent
Lyman: 7 percent
Rock outcrop: 5 percent
Knob Lock: 3 percent
Sunapee: 2 percent

The Becket, Lyman, Knob Lock, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Becket, Lyman, and Knob Lock soils occupy similar positions, but Becket soils have a dense substratum; Lyman soils are shallow to bedrock; and Knob Lock soils are shallow to very shallow to bedrock, and are organic. Sunapee soils are on drainageways. Included areas can occupy about 25 percent of this unit.

27 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones, and the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.

- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MoA—Mooers loamy fine sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and moderately well drained. It is on footslopes of deltas, outwash plains, and stream terraces in the Adirondack Upland. Areas range from 3 to 125 acres in size.

Map Unit Composition

Major Components
Mooers: 85 percent

Inclusions
Champlain: 5 percent
Nicholville: 4 percent
Croghan: 3 percent
Unnamed: 2 percent
Sunapee: 1 percent

The somewhat excessively drained Champlain, Nicholville, Croghan, and Sunapee soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained sandy soils that lack a spodic horizon. Champlain soils occupy higher positions. Nicholville, Croghan, and Sunapee soils occupy similar positions, but Nicholville soils are silty. Sunapee soils are loamy, and all three have a spodic horizon. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2w
Hydric soil rating:
  Mooers: no
Hydrologic group:
  Mooers: A/D

Soil Properties and Qualities

Mooers
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: proglacial deltas, proglacial outwash plains, proglacial stream terraces
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock

Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 4 inches: strongly acid to slightly acid (5.1 to 6.5)
- 4 to 16 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 16 to 22 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 22 to 42 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 42 to 58 inches: moderately acid to slightly alkaline (5.6 to 7.8)
- 58 to 72 inches: moderately acid to slightly alkaline (5.6 to 7.8)

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 4 inches: rapid (6 to 20 inches/hour)
- 4 to 16 inches: rapid (6 to 20 inches/hour)
- 16 to 22 inches: rapid (6 to 20 inches/hour)
- 22 to 42 inches: rapid (6 to 20 inches/hour)
- 42 to 58 inches: rapid (6 to 20 inches/hour)
- 58 to 72 inches: rapid (6 to 20 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations due to seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.

MuC—Mundalite fine sandy loam, 8 to 15 percent slopes, very bouldery

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 5 to 375 acres in size.

Map Unit Composition

Major Components
Mundalite, very bouldery: 85 percent

Inclusions
Ampersand: 5 percent
Rawsonville: 4 percent
Becket: 3 percent
Unnamed: 3 percent

The somewhat poorly drained Ampersand, Rawsonville, and Becket soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Ampersand soils occupy lower positions. Rawsonville and Becket soils occupy similar positions, but Rawsonville soils are moderately deep to bedrock, and Becket

soils have less organic matter in the subsoil. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Mundalite, very bouldery: no
Hydrologic group:
  Mundalite, very bouldery: C

Soil Properties and Qualities

Mundalite, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 25 to 40 inches to densic material
Depth to seasonal high water table: 25 to 40 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
  3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
  5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
  14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
  27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
  37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
  1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  14 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  27 to 37 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
  37 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations due to very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

MuD—Mundalite fine sandy loam, 15 to 35 percent slopes, very bouldery

Setting

This soil is loamy, very deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 5 to 140 acres in size.

Map Unit Composition

Major Components
Mundalite, very bouldery: 85 percent

5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 to 37 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
37 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture

- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads due to seasonal wetness.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.

- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

MwC—Mundalite-Rawsonville complex, 3 to 15 percent slopes, rocky, very bouldery

Setting

These soils are loamy, very deep and moderately deep, strongly sloping, and well drained. They are on backslopes and shoulders of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 55 acres in size.

Map Unit Composition

Major Components
Mundalite, rocky, very bouldery: 45 percent
Rawsonville, rocky, very bouldery: 30 percent

Inclusions
Ampersand: 5 percent
Becket: 5 percent
Hogback: 5 percent
Knob Lock: 5 percent
Unnamed: 4 percent
Rock outcrop: 1 percent

The somewhat poorly drained Ampersand, Becket, Hogback, and Knob Lock soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Ampersand soils occupy lower positions than Mundalite soils. Becket, Hogback, and Knob Lock soils occupy similar positions, but Becket soils have less organic matter in the subsoil; Hogback soils are shallow to bedrock; and Knob Lock soils are shallow and very shallow to bedrock and are organic. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Mundalite, rocky, very bouldery: no
  Rawsonville, rocky, very bouldery: no
Hydrologic group:
  Mundalite, rocky, very bouldery: C
  Rawsonville, rocky, very bouldery: B

Soil Properties and Qualities

Mundalite, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 25 to 40 inches to densic material
Depth to seasonal high water table: 25 to 40 inches
  Water table kind: perched
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides

Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
3 to 5 inches: extremely acid to moderately acid (3.5 to 6.0)
5 to 14 inches: extremely acid to moderately acid (3.5 to 6.0)
14 to 27 inches: extremely acid to moderately acid (3.5 to 6.0)
27 to 37 inches: very strongly acid to slightly acid (4.5 to 6.5)
37 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
0 to 1 inch: moderate or moderately rapid (0.6 to 6 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
5 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 to 37 inches: slow or moderately slow (0.06 to 0.6 inches/hour)
37 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Rawsonville, rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
2 to 3 inches: extremely acid to strongly acid (3.5 to 5.5)
3 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
5 to 11 inches: extremely acid to strongly acid (3.5 to 5.5)
11 to 20 inches: extremely acid to strongly acid (3.5 to 5.5)
20 to 25 inches: extremely acid to strongly acid (3.5 to 5.5)
25 inches, bedrock
Permeability:
0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

11 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
20 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
25 inches, bedrock

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture

- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

MwD—Mundalite-Rawsonville complex, 15 to 35 percent slopes, rocky, very bouldery

Setting

These soils are loamy, very deep and moderately deep, moderately steep and steep, and well drained. They are on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 10 to 235 acres in size.

Map Unit Composition

Major Components
Mundalite, rocky, very bouldery: 45 percent
Rawsonville, rocky, very bouldery: 30 percent

Inclusions
Becket: 5 percent
Hogback: 5 percent
Knob Lock: 5 percent
Rock outcrop: 5 percent

Unnamed: 4 percent
Ampersand: 1 percent

The Becket, Hogback, Knob Lock, and somewhat poorly drained Ampersand soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Becket, Hogback, and Knob Lock soils occupy similar positions, but Becket soils have less organic matter in the subsoil; Hogback soils are shallow to bedrock; and Knob Lock soils are shallow and very shallow to bedrock and are organic. Ampersand soils occupy lower positions than Mundalite soils. Included areas can occupy about 25 percent of this unit.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- The slope may restrict the use of most farm equipment.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Locating haul roads on soils that are deeper to bedrock, or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.

- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations due to very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

NaA—Naumburg loamy fine sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and somewhat poorly drained. It is on footslopes of deltas, outwash plains, and stream terraces in the Adirondack Upland. Areas range from 3 to 105 acres in size.

Map Unit Composition

Major Components
Naumburg: 85 percent

Inclusions
Searsport: 5 percent
Croghan: 4 percent
Roundabout: 3 percent
Tahawus: 2 percent
Unnamed: 1 percent

The very poorly drained Searsport and Tahawus, moderately well drained Croghan, and Roundabout soils may be included in areas of this map unit. Also included are small areas of poorly drained sandy soils. Searsport and Tahawus soils occupy lower positions, and Tahawus soils are underlain by till. Croghan soils occupy higher positions. Roundabout soils occupy similar positions, but are silty. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3w
Hydric soil rating:
    Naumburg: no
Hydrologic group:
    Naumburg: A/D

Soil Properties and Qualities

Naumburg

Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Landform: deltas, outwash plains, stream terraces
Parent material: sandy glaciolacustrine deposits derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 7 inches: extremely acid to strongly acid (3.5 to 5.5)
  7 to 10 inches: extremely acid to strongly acid (3.5 to 5.5)
  10 to 18 inches: extremely acid to strongly acid (3.5 to 5.5)
  18 to 31 inches: extremely acid to strongly acid (3.5 to 5.5)
  31 to 54 inches: very strongly acid to slightly acid (4.5 to 6.5)
  54 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  2 to 7 inches: rapid (6 to 20 inches/hour)
  7 to 10 inches: rapid (6 to 20 inches/hour)
  10 to 18 inches: rapid (6 to 20 inches/hour)
  18 to 31 inches: rapid (6 to 20 inches/hour)
  31 to 54 inches: rapid or very rapid (6 to 100 inches/hour)
  54 to 72 inches: rapid or very rapid (6 to 100 inches/hour)

Use and Management

Cropland

- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.

- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

NeB—Nellis fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and well drained. It is on summits, shoulders, and backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 70 acres in size.

Map Unit Composition

Howard: 1 percent
Pittsfield: 1 percent

The moderately well drained Amenia, Bombay, and Cayuga, somewhat poorly drained Massena, somewhat excessively drained Howard, and Pittsfield soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Amenia, Bombay, and Cayuga soils occupy slightly lower positions; Bombay soils have slightly higher clay content in the subsoil; and Cayuga soils are clayey over loamy. Massena soils are on small depressions and drainageways. Howard and Pittsfield soils occupy similar positions, but Howard soils are loamy and gravelly, and Pittsfield soils have a lower pH. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Shrink-swell potential: low
Surface runoff potential: low
Landform: drumlinoid ridges
Parent material: loamy lodgment till derived from limestone
Reaction (pH):
  0 to 9 inches: moderately acid to neutral (5.6 to 7.3)
  9 to 16 inches: moderately acid to neutral (5.6 to 7.3)
  16 to 21 inches: moderately acid to neutral (5.6 to 7.3)
  21 to 26 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  26 to 37 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  37 to 60 inches: neutral to moderately alkaline (6.6 to 8.4)
  60 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)
Permeability:
  0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 16 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

16 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
21 to 26 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
26 to 37 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
37 to 60 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
60 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

NeC—Nellis fine sandy loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 150 acres in size.

Map Unit Composition

Major Components
Nellis: 85 percent

Inclusions
Amenia: 5 percent
Pittsfield: 3 percent
Bombay: 2 percent

Unnamed: 2 percent

  37 to 60 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  60 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

NeD—Nellis fine sandy loam, 15 to 25 percent slopes

Setting

This soil is loamy, very deep, moderately steep, and well drained. It is on backslopes of drumlinoid ridges in the Champlain Valley. Areas range from 3 to 75 acres in size.

Map Unit Composition

Major Components
Nellis: 85 percent

Inclusions
Pittsfield: 5 percent
Unnamed: 4 percent
Howard: 3 percent
Cayuga: 2 percent
Amenia: 1 percent

The Pittsfield, somewhat excessively drained Howard, and moderately well drained Cayuga and Amenia soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Howard and Pittsfield soils occupy similar positions, but Howard soils are loamy and gravelly, and Pittsfield soils have a lower pH.

Amenia and Cayuga soils occupy slightly lower positions, and Cayuga soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

37 to 60 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
60 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.

- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

NgA—Niagara silt loam, 0 to 3 percent slopes

Setting

This soil is silty and clayey, very deep, nearly level, and somewhat poorly drained. It is on footslopes of lake plains in the Champlain Valley. Areas range from 3 to 90 acres in size.

Map Unit Composition

Major Components
Niagara: 85 percent

Inclusions
Covington: 5 percent
Collamer: 4 percent
Cosad: 3 percent
Tonawanda: 2 percent
Churchville: 1 percent

The poorly drained Covington, moderately well drained Collamer, Cosad, Tonawanda, and Churchville soils may be included in areas of this map unit. Also included are areas that have a slightly higher clay content. Covington soils occupy slightly lower positions and are clayey. Collamer soils occupy higher positions. Cosad, Tonawanda, and Churchville soils occupy similar positions, but Cosad soils are sandy over clayey, Tonawanda soils are silty, and Churchville soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

    35 to 48 inches: slow to moderate (0.06 to 2 inches/hour)
    48 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

Cropland
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- These soils are well suited to pasture.

- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The potential for shrink-swell in these soils results in a limited capacity to support a load without movement and may cause shifting foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

NgB—Niagara silt loam, 3 to 8 percent slopes

Setting

This soil is silty and clayey, very deep, gently sloping, and somewhat poorly drained. It is on footslopes of lake plains in the Champlain Valley. Areas range from 4 to 60 acres in size.

Map Unit Composition

Major Components
Niagara: 85 percent

Inclusions
Collamer: 5 percent
Covington: 4 percent
Cosad: 3 percent
Tonawanda: 2 percent
Churchville: 1 percent

The moderately well drained Collamer, poorly drained Covington, Cosad, Tonawanda, and Churchville soils may be included in areas of this map unit. Collamer soils occupy higher positions. Covington soils occupy slightly lower positions and are clayey. Cosad, Tonawanda, and Churchville soils occupy similar positions, but Cosad soils are sandy over clayey; Tonawanda soils are silty; and Churchville soils are clayey over loamy. Included areas can occupy about 15 percent of this unit.

- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

NvB—Nicholville silt loam, 3 to 8 percent slopes

Setting

This soil is silty, very deep, gently sloping, and moderately well drained. It is on backslopes and footslopes of glacial valley walls in the Adirondack Upland. Areas range from 3 to 70 acres in size.

Map Unit Composition

Major Components
Nicholville: 85 percent

Inclusions
Roundabout: 4 percent
Depeyster: 3 percent
Champlain: 2 percent
Fernlake: 2 percent
Hailesboro: 2 percent
Unnamed: 2 percent

The somewhat poorly drained Roundabout and Hailesboro, Depeyster, and somewhat excessively drained Champlain and Fernlake soils may be included in areas of this map unit. Also included are small areas of well drained silty soils. Roundabout and Hailesboro soils occupy slightly lower positions, and Hailesboro soils are silty and clayey. Depeyster soils occupy similar positions, but are silty and clayey. Champlain and Fernlake soils occupy higher positions, both are sandy, and Fernlake soils are underlain by till. Included areas can occupy about 15 percent of this unit.

38 to 54 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
54 to 72 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

OmA—Occum fine sandy loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and well drained. It is on flood plains in the Champlain Valley (fig. 22). Areas range from 3 to 75 acres in size.

Map Unit Composition

Major Components
Occum: 85 percent

Inclusions
Pootatuck: 5 percent
Factoryville: 3 percent
Rippowam: 3 percent
Unnamed: 3 percent
Fluvaquents-Udifluvents: 1 percent

The moderately well drained Pootatuck, Factoryville, poorly drained Rippowam, and somewhat poorly and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained loamy flood plain soils. Pootatuck soils occupy slightly lower positions. Factoryville soils occupy similar positions, but are sandy. Rippowam soils are on small depressions. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 1
Hydric soil rating:
    Occum: no
Hydrologic group:
    Occum: A

Figure 22.—This photo illustrates a good example of a well drained Occum fine sandy loam alluvial terrace adjacent to the Boquet River, northwest of Wadhams in the town of Essex. These soils are class 1 agricultural lands and are potentially highly productive. Unfortunately, there are few acres of it in the county and they are fragmented into small irregular shaped pieces by the river, making them difficult to manage for crop production. Many are used for hay or pasture like this map unit. This map unit, at the time the photo was taken, was undergoing severe undercutting and streambank erosion from the river. The NRCS, Essex County Soil & Water Conservation District, and the Boquet River Association (a local environmental group), work with landowners to initiate streambank stabilization projects such as cribbing structures and willow plantings to help protect and enhance water quality in the river.

Soil Properties and Qualities

Occum
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: occasional
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very low
Landform: flood plains
Parent material: loamy alluvium derived from igneous and sedimentary rock
Reaction (pH):
- 0 to 9 inches: very strongly acid to slightly acid (4.5 to 6.5)
- 9 to 21 inches: very strongly acid to slightly acid (4.5 to 6.5)
- 21 to 30 inches: very strongly acid to slightly acid (4.5 to 6.5)
- 30 to 36 inches: very strongly acid to slightly acid (4.5 to 6.5)
- 36 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)

Permeability:
- 0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 9 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 21 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

30 to 36 inches: moderately rapid to very rapid (2 to 100 inches/hour)
36 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Flooding may delay planting or damage crops in some years.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.

Woodland
- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

OwA—Ondawa sandy loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and well drained. It is on flood plains in the Adirondack Upland. Areas range from 3 to 95 acres in size.

Map Unit Composition

Major Components
Ondawa: 85 percent

Inclusions
Podunk: 5 percent
Champlain: 3 percent
Rumney: 3 percent
Unnamed: 3 percent
Fluvaquents-Udifluvents: 1 percent

The moderately well drained Podunk, somewhat excessively drained Champlain, poorly drained Rumney, and somewhat poorly and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained, loamy flood plain soils. Podunk soils occupy slightly lower positions. Champlain soils occupy similar positions, but are sandy. Rumney soils are on small depressions. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 1
Hydric soil rating:
  Ondawa: no
Hydrologic group:
  Ondawa: A

Soil Properties and Qualities

Ondawa
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: occasional
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very low
Landform: flood plains
Parent material: loamy alluvium derived from gneiss
Reaction (pH):
  0 to 9 inches: very strongly acid to slightly acid (4.5 to 6.5)
  9 to 21 inches: very strongly acid to slightly acid (4.5 to 6.5)
  21 to 34 inches: very strongly acid to slightly acid (4.5 to 6.5)
  34 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
  0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  21 to 34 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  34 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.

- Flooding may delay planting or damage crops in some years.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Pc—Pits, quarry

Setting

This map unit consists of areas of exposed bedrock with some quarry or mine spoil debris. Slopes range from nearly level to vertical. These areas are found in old limestone quarries in the Champlain Valley, and in abandoned and active granite quarries, and open pit mines in the Adirondack Upland. Areas range from 5 to 50 acres in size.

Map Unit Composition

Major Components
Pits, quarry: 85 percent

Inclusions
Farmington: 4 percent
Lyman: 4 percent
Tunbridge: 4 percent
Chatfield: 2 percent
Hollis: 1 percent

The well drained Farmington, Lyman, Tunbridge, Chatfield, and Hollis soils may be included in areas of this map unit. They occupy small areas within or along the fringes of the quarry. Farmington, Lyman, and Hollis soils are loamy and shallow to bedrock, and Tunbridge and Chatfield soils are loamy and moderately deep to bedrock. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 8s
Hydric soil rating: unranked
Hydrologic group: unranked

This component is too variable to define the range of characteristics. Onsite investigation is needed to determine the suitability for specific uses.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the exposed bedrock.

Pasture
- These soils are generally unsuited to use as pasture because of the exposed bedrock.

Woodland
- These areas are generally unsuited for commercial woodland use because of the exposed bedrock.

Development
- These areas are generally unsuited for development because of the exposed bedrock.

Pd—Pits, sand and gravel

Setting

This map unit consists of areas of active or abandoned sand or gravel mining operations. Slopes range from nearly level to vertical. Some of these areas may be reclaimed with native subsoil material and smoothed. These areas are found on deltas, outwash plains, and kame terraces throughout the county. Areas range from 3 to 80 acres in size.

Map Unit Composition

Major Components
Pits, sand and gravel: 85 percent

Inclusions
Adams: 3 percent
Colton: 3 percent
Howard: 3 percent
Monadnock: 3 percent
Windsor: 3 percent

The somewhat excessively drained Adams, excessively drained Colton and Windsor, and well drained Howard and Monadnock soils may be included in areas of this map unit. They occupy small areas within or along the fringes of the sand or gravel pit. Adams and Windsor soils are sandy; Colton soils are sandy and gravelly; Howard soils are loamy and gravelly; and Monadnock soils are loamy over sandy or gravelly and underlain by till. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 8s
Hydric soil rating: unranked
Hydrologic group: unranked

This component is too variable to define the range of characteristics. Onsite investigation is needed to determine the suitability for specific uses.

Use and Management

Cropland
- These areas are generally unsuited to use as cropland.

Pasture
- Some reclaimed areas may be used for pasture. Onsite investigation is needed to determine forage species to plant and various conservation practices to employ.

Woodland
- Some areas may be reclaimed for commercial woodland use. Onsite investigation is needed to determine tree species to plant and various conservation practices to employ.

Development
- Some areas may be reclaimed for development. Onsite investigation is needed to determine various engineering and conservation practices to employ.

PfB—Pittsfield loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and well drained. It is on summits and shoulders of glaciated hills and till plains in the Champlain Valley. Areas range from 3 to 80 acres in size.

Map Unit Composition

Major Components
Pittsfield: 85 percent

Inclusions
Georgia: 5 percent
Massena: 3 percent
Unnamed: 3 percent
Charlton: 2 percent

Chatfield: 1 percent
Nellis: 1 percent

The moderately well drained Georgia, somewhat poorly drained Massena, Charlton, Chatfield, and Nellis soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Georgia soils occupy slightly lower positions. Massena soils are on small depressions or drainageways. Charlton, Chatfield, and Nellis soils occupy similar positions, but Charlton soils have a lower pH; Chatfield soils are moderately deep to bedrock and have a lower pH; and Nellis soils have a higher pH. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e
Hydric soil rating:
  Pittsfield: no
Hydrologic group:
  Pittsfield: A

Soil Properties and Qualities

Pittsfield
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Landform: glaciated till plains, glaciated hills
Parent material: loamy ablation till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 8 inches: very strongly acid to neutral (4.5 to 7.3)
  8 to 10 inches: strongly acid to neutral (5.1 to 7.3)
  10 to 20 inches: strongly acid to neutral (5.1 to 7.3)
  20 to 24 inches: strongly acid to neutral (5.1 to 7.3)
  24 to 30 inches: moderately acid to neutral (5.6 to 7.3)
  30 to 45 inches: moderately acid to neutral (5.6 to 7.3)
  45 to 59 inches: moderately acid to moderately alkaline (5.6 to 8.4)
  59 to 72 inches: moderately acid to moderately alkaline (5.6 to 8.4)
Permeability:
  0 to 8 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  8 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  10 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  20 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  24 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  30 to 45 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  45 to 59 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  59 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.

- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

PfC—Pittsfield loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hills and till plains in the Champlain Valley. Areas range from 3 to 50 acres in size.

Map Unit Composition

Major Components
Pittsfield: 85 percent

Inclusions
Georgia: 5 percent
Charlton: 4 percent
Unnamed: 3 percent
Chatfield: 1 percent

    8 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    10 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    20 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    24 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    30 to 45 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    45 to 59 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
    59 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

PfD—Pittsfield loam, 15 to 25 percent slopes

Setting

This soil is loamy, very deep, moderately steep, and well drained. It is on backslopes of glaciated hills and till plains in the Champlain Valley. Areas range from 5 to 55 acres in size.

Map Unit Composition

Major Components
Pittsfield: 85 percent

Inclusions
Charlton: 6 percent
Unnamed: 4 percent
Chatfield: 3 percent
Georgia: 1 percent
Nellis: 1 percent

The moderately well drained Georgia, Charlton, Chatfield, and Nellis soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Georgia soils are on drainageways. Charlton, Chatfield, and Nellis soils occupy similar positions, but Charlton soils have a lower pH; Chatfield soils are moderately deep to bedrock and have a lower pH; and Nellis soils have a higher pH. Included areas can occupy about 15 percent of this unit.

20 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
24 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
30 to 45 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
45 to 59 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
59 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining

properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

PfE—Pittsfield loam, 25 to 45 percent slopes

Setting

This soil is loamy, very deep, very steep, and well drained. It is on backslopes of glaciated hills and till plains in the Champlain Valley. Areas range from 3 to 35 acres in size.

30 to 45 inches: moderately acid to neutral (5.6 to 7.3)
45 to 59 inches: moderately acid to moderately alkaline (5.6 to 8.4)
59 to 72 inches: moderately acid to moderately alkaline (5.6 to 8.4)
Permeability:
0 to 8 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
8 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
10 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
20 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
24 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
30 to 45 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
45 to 59 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
59 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.

- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

PkA—Pleasant Lake peat, 0 to 2 percent slopes

Setting

This soil is mucky, very deep, nearly level, and very poorly drained. It is on bogs and swamps in the Adirondack Upland. Areas range from 3 to 115 acres in size.

Map Unit Composition

Major Components
Pleasant Lake: 85 percent

Inclusions
Burnt Vly: 5 percent
Bucksport: 4 percent
Wonsqueak: 3 percent
Rumney: 2 percent
Tahawus: 1 percent

The Burnt Vly, Bucksport, Wonsqueak, poorly drained Rumney, and Tahawus soils may be included in areas of this map unit. Burnt Vly, Bucksport and Wonsqueak soils occupy similar positions, but Burnt Vly and Wonsqueak soils are less than 51 inches deep to mineral soil material, and Bucksport and Wonsqueak soils have a higher pH. Rumney soils are loamy and are on small flood plain areas near streams. Tahawus

soils occupy similar positions, but are sandy and are on small areas underlain by till. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
  Pleasant Lake: yes
Hydrologic group:
  Pleasant Lake: B/D

Soil Properties and Qualities

Pleasant Lake
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
  Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: not rated
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material
Reaction (pH):
  0 to 4 inches: ultra acid or extremely acid (1.8 to 4.4)
  4 to 5 inches: ultra acid or extremely acid (1.8 to 4.4)
  5 to 9 inches: ultra acid or extremely acid (1.8 to 4.4)
  9 to 31 inches: ultra acid or extremely acid (1.8 to 4.4)
  31 to 44 inches: ultra acid or extremely acid (1.8 to 4.4)
  44 to 53 inches: ultra acid or extremely acid (1.8 to 4.4)
  53 to 66 inches: ultra acid or extremely acid (1.8 to 4.4)
Permeability:
  0 to 4 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  4 to 5 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  5 to 9 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  9 to 31 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  31 to 44 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  44 to 53 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  53 to 66 inches: moderately slow to rapid (0.2 to 20 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.

- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The organic matter content limits soil strength and severely affects the capacity of these soils to bear a load without movement.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields

- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets

- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.

PlB—Pittsfield-Chatfield complex, 3 to 8 percent slopes, rocky, very stony

Setting

These soils are loamy, very deep and moderately deep, gently sloping, and well drained. They are on summits and shoulders of glaciated hills in the Champlain Valley. Areas range from 3 to 75 acres in size.

Map Unit Composition

Major Components
Pittsfield, rocky, very stony: 45 percent
Chatfield, rocky, very stony: 30 percent

Inclusions
Hollis: 8 percent
Unnamed: 6 percent
Charlton: 4 percent
Georgia: 2 percent
Massena: 2 percent
Cayuga: 1 percent
Nellis: 1 percent
Rock Outcrop: 1 percent

The Hollis, Charlton, Nellis, moderately well drained Georgia and Cayuga, and somewhat poorly drained Massena soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Hollis, Charlton, and Nellis soils occupy similar positions, but Hollis soils are shallow to bedrock; Charlton soils have a lower pH; and Nellis soils have a higher pH. Georgia and Cayuga soils occupy slightly lower positions, and Cayuga soils are clayey over loamy. Massena soils are on small depressions or drainageways. Included areas can occupy about 25 percent of this unit.

19 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
27 to 32 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
32 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused

by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock in some areas reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

PlC—Pittsfield-Chatfield complex, 8 to 15 percent slopes, rocky, very stony

Setting

These soils are loamy, very deep and moderately deep, strongly sloping, and well drained. They are on shoulders and backslopes of glaciated hills in the Champlain Valley. Areas range from 3 to 80 acres in size.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones.

Pasture
- The slope may restrict the use of most farm equipment.
- Avoiding overgrazing can reduce the hazard of erosion.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads due to steep slopes.
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

PlF—Pittsfield-Chatfield complex, 35 to 60 percent slopes, rocky, very stony

Setting

These soils are loamy, very deep and moderately deep, very steep, and well drained. They are on backslopes of glaciated hills in the Champlain Valley. Areas range from 10 to 195 acres in size.

Map Unit Composition

Major Components

Pittsfield, rocky, very stony: 45 percent
Chatfield, rocky, very stony: 30 percent

Inclusions

Hollis: 9 percent
Unnamed: 7 percent
Charlton: 6 percent
Cayuga: 1 percent
Nellis: 1 percent
Rock outcrop: 1 percent

The Hollis, Charlton, Nellis, and moderately well drained Cayuga soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Hollis, Charlton, and Nellis soils occupy similar positions, but Hollis soils

are shallow to bedrock, Charlton soils have a lower pH, and Nellis soils have a higher pH. Cayuga soils occupy slightly lower positions, and are clayey over loamy. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
  Pittsfield, rocky, very stony: no
  Chatfield, rocky, very stony: no
Hydrologic group:
  Pittsfield, rocky, very stony: A
  Chatfield, rocky, very stony: B

Soil Properties and Qualities

Pittsfield, rocky, very stony
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy ablation till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 8 inches: very strongly acid to neutral (4.5 to 7.3)
  8 to 10 inches: strongly acid to neutral (5.1 to 7.3)
  10 to 20 inches: strongly acid to neutral (5.1 to 7.3)
  20 to 24 inches: strongly acid to neutral (5.1 to 7.3)
  24 to 30 inches: moderately acid to neutral (5.6 to 7.3)
  30 to 45 inches: moderately acid to neutral (5.6 to 7.3)
  45 to 59 inches: moderately acid to moderately alkaline (5.6 to 8.4)
  59 to 72 inches: moderately acid to moderately alkaline (5.6 to 8.4)
Permeability:
  0 to 8 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  8 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  10 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  20 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  24 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  30 to 45 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  45 to 59 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  59 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Chatfield, rocky, very stony
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate

Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony
Landform: glaciated hills
Parent material: loamy till derived from igneous and sedimentary rock
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 7 inches: very strongly acid to moderately acid (4.5 to 6.0)
- 7 to 19 inches: very strongly acid to moderately acid (4.5 to 6.0)
- 19 to 27 inches: very strongly acid to moderately acid (4.5 to 6.0)
- 27 to 32 inches: very strongly acid to moderately acid (4.5 to 6.0)
- 32 inches, bedrock

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 19 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 27 to 32 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 32 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones, and the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

PoA—Podunk very fine sandy loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and moderately well drained. It is on flood plains in the Adirondack Upland. Areas range from 3 to 145 acres in size.

Map Unit Composition

Major Components
Podunk: 85 percent

Inclusions
Ondawa: 5 percent
Lovewell: 3 percent
Mooers: 3 percent
Rumney: 3 percent
Fluvaquents-Udifluvents: 1 percent

The well drained Ondawa, Lovewell, Mooers, poorly drained Rumney, and somewhat poorly drained and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Ondawa soils occupy higher positions. Lovewell and Mooers soils occupy similar positions, but Lovewell soils are silty, and Mooers soils are sandy. Rumney soils are on small depressions. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2w
Hydric soil rating:
Podunk: no
Hydrologic group:
Podunk: A/D

Soil Properties and Qualities

Podunk
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
Water table kind: apparent
Flooding: occasional
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Landform: flood plains
Parent material: loamy alluvium derived from gneiss
Reaction (pH):
0 to 7 inches: very strongly acid to slightly acid (4.5 to 6.5)
7 to 11 inches: very strongly acid to slightly acid (4.5 to 6.5)
11 to 18 inches: very strongly acid to slightly acid (4.5 to 6.5)
18 to 31 inches: very strongly acid to slightly acid (4.5 to 6.5)
31 to 34 inches: very strongly acid to slightly acid (4.5 to 6.5)
34 to 39 inches: very strongly acid to slightly acid (4.5 to 6.5)
39 to 45 inches: very strongly acid to slightly acid (4.5 to 6.5)
45 to 53 inches: very strongly acid to slightly acid (4.5 to 6.5)
53 to 72 inches: very strongly acid to slightly acid (4.5 to 6.5)
Permeability:
0 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
7 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
11 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
18 to 31 inches: moderately rapid to very rapid (2 to 100 inches/hour)
31 to 34 inches: moderately rapid to very rapid (2 to 100 inches/hour)
34 to 39 inches: moderately rapid to very rapid (2 to 100 inches/hour)
39 to 45 inches: moderately rapid to very rapid (2 to 100 inches/hour)
45 to 53 inches: moderately rapid to very rapid (2 to 100 inches/hour)
53 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Flooding may delay planting or damage crops in some years.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Conducting road construction and harvesting operations during months of low stream flow, and use of riparian buffers will help overcome construction limitations of haul roads caused by occasional flooding.
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Limiting construction of log landings on occasionally flooded soils, and conducting harvesting operations during months when flooding is least likely to occur will help overcome these limitations. Riparian setbacks should be at least 200 feet.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements

- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.

- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The PoA map unit have very fine sandy loam textures in the upper solum that are not typical for the range of the Podunk series. This should not significantly affect use and management on a local basis for most purposes.

PrA—Pootatuck fine sandy loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and moderately well drained. It is on flood plains in the Champlain Valley. Areas range from 3 to 85 acres in size.

Map Unit Composition

Major Components
Pootatuck: 85 percent

Inclusions
Occum: 5 percent
Deerfield: 3 percent
Rippowam: 3 percent
Unnamed: 3 percent
Fluvaquents-Udifluvents: 1 percent

The well drained Occum, Deerfield, poorly drained Rippowam, and somewhat poorly drained and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained loamy flood plain soils. Occum soils occupy higher positions. Deerfield soils occupy similar positions, but are sandy. Rippowam soils are on small depressions. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

PtB—Pyrities fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and well drained. It is on summits and shoulders of glaciated hills in the Adirondack Upland. Areas range from 3 to 425 acres in size.

Map Unit Composition

Major Components
Pyrities: 85 percent

Inclusions
Kalurah: 5 percent
Becket: 4 percent
Monadnock: 3 percent
Malone: 2 percent
Nehasne: 1 percent

The moderately well drained Kalurah, Becket, Monadnock, somewhat poorly drained Malone, and Nehasne soils may be included in areas of this map unit. Kalurah soils occupy slightly lower positions. Becket and Monadnock soils occupy similar positions, but both have a spodic horizon, Becket soils have a dense substratum, and Monadnock soils are loamy over sandy or gravelly. Malone soils are on small depressions or drainageways. Nehasne soils occupy similar positions, but are moderately deep to bedrock. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

- 28 to 54 inches: slow to moderately rapid (0.06 to 6 inches/hour)
- 54 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- These soils have no restrictions for commercial woodland use.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

PtC—Pyrities fine sandy loam, 8 to 15 percent slopes

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on shoulders and backslopes of glaciated hills in the Adirondack Upland. Areas range from 3 to 555 acres in size.

Map Unit Composition

Major Components
Pyrities: 85 percent

Inclusions

Use and Management

Cropland

- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

PtD—Pyrities fine sandy loam, 15 to 25 percent slopes

Setting

This soil is loamy, very deep, moderately steep, and well drained. It is on backslopes of glaciated hills in the Adirondack Upland. Areas range from 3 to 100 acres in size.

Becket: 4 percent

Unnamed: 3 percent
Kalurah: 2 percent
Nehasne: 1 percent

The Monadnock, Becket, moderately well drained Kalurah, and Nehasne soils may be included in areas of this map unit. Also included are areas with a very stony surface. Becket and Monadnock soils occupy similar positions, but both have a spodic horizon; Becket soils have a dense substratum; and Monadnock soils are loamy over sandy or gravelly. Kalurah soils are on drainageways. Nehasne soils occupy similar positions, but are moderately deep to bedrock. Included areas can occupy about 15 percent of this unit.

  20 to 28 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  28 to 54 inches: slow to moderately rapid (0.06 to 6 inches/hour)
  54 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

PuC—Pyrities fine sandy loam, 8 to 15 percent slopes, very stony

Setting

This soil is loamy, very deep, strongly sloping, and well drained. It is on summits, shoulders, and backslopes of glaciated hills in the Adirondack Upland. Areas range from 3 to 260 acres in size.

Map Unit Composition

Major Components
Pyrities, very stony: 85 percent

Inclusions
Monadnock: 5 percent
Becket: 4 percent
Kalurah: 3 percent
Malone: 2 percent
Nehasne: 1 percent

The Monadnock, Becket, moderately well drained Kalurah, somewhat poorly drained Malone, and Nehasne soils may be included in areas of this map unit. Becket and Monadnock soils occupy similar positions, but both have a spodic horizon; Becket soils have a dense substratum; and Monadnock soils are loamy over sandy or gravelly. Kalurah soils occupy slightly lower positions. Malone soils are on small depressions or drainageways. Nehasne soils occupy similar positions, but are moderately deep to bedrock. Included areas can occupy about 15 percent of this unit.

54 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability due to strongly sloping areas.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

PuD—Pyrities fine sandy loam, 15 to 35 percent slopes, very stony

Setting

This soil is loamy, very deep, moderately steep and steep, and well drained. It is on backslopes of glaciated hills in the Adirondack Upland. Areas range from 3 to 345 acres in size.

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.

- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

PwD—Pyrities-Nehasne complex, 15 to 35 percent slopes, rocky, very stony

The moderately well drained Kalurah, Lyman, Becket, Monadnock, and somewhat poorly drained Malone soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Kalurah soils occupy slightly lower positions than Pyrities soils. Lyman, Becket, and Monadnock soils occupy similar positions, but all have a spodic horizon; Lyman soils are shallow to bedrock; Becket soils have a dense substratum; and Monadnock soils are loamy over sandy or gravelly. Malone soils are on small depressions or drainageways. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3e
Hydric soil rating:
  Pyrities: no
  Nehasne: no
Hydrologic group:
  Pyrities: A
  Nehasne: B

Soil Properties and Qualities

Pyrities
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Landform: glaciated hills

Parent material: loamy lodgment till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 4 inches: moderately acid to neutral (5.6 to 7.3)
  4 to 7 inches: moderately acid to neutral (5.6 to 7.3)
  7 to 11 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  11 to 20 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  20 to 28 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  28 to 54 inches: slightly acid to moderately alkaline (6.1 to 8.4)
  54 to 72 inches: slightly acid to moderately alkaline (6.1 to 8.4)
Permeability:
  0 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  7 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  11 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  20 to 28 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  28 to 54 inches: slow to moderately rapid (0.06 to 6 inches/hour)
  54 to 72 inches: slow to moderately rapid (0.06 to 6 inches/hour)

Nehasne
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Landform: glaciated hills
Parent material: loamy till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 6 inches: moderately acid or slightly acid (5.6 to 6.5)
  6 to 13 inches: slightly acid or neutral (6.1 to 7.3)
  13 to 20 inches: slightly acid or neutral (6.1 to 7.3)
  20 to 25 inches: neutral or slightly alkaline (6.6 to 7.8)
  25 inches, bedrock
Permeability:
  0 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  6 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  13 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  20 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  25 inches, bedrock

Use and Management

Cropland
- The rooting depth of some crops may be restricted by bedrock.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

PyD—Pyrities-Nehasne complex, 15 to 25 percent slopes, rocky

Setting

These soils are loamy, very deep and moderately deep, moderately steep, and well drained. They are on backslopes of glaciated hills in the Adirondack Upland. Areas range from 3 to 50 acres in size.

Map Unit Composition

Major Components
Pyrities: 45 percent
Nehasne: 30 percent

Inclusions
Becket: 5 percent
Lyman: 5 percent
Rock outcrop: 5 percent
Kalurah: 4 percent
Monadnock: 4 percent
Unnamed: 2 percent

The moderately well drained Kalurah, Lyman, Becket, and Monadnock soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Kalurah soils occupy slightly lower positions than Pyrities soils. Lyman, Becket, and Monadnock soils occupy similar positions, but all have a spodic horizon; Lyman soils are shallow to bedrock; Becket soils have a dense substratum; and Monadnock soils are loamy over sandy or gravelly. Included areas can occupy about 25 percent of this unit.

Use and Management

Cropland
- The rooting depth of some crops may be restricted by bedrock.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Locating haul roads on soils that are deeper to bedrock, or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.

- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock may limit site preparation such as shaping and grading and restrict installation of roads and streets.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

RaC—Rawsonville-Hogback complex, 8 to 15 percent slopes, very rocky, very bouldery

Setting

These soils are loamy, moderately deep and shallow, strongly sloping, and well drained. They are on summits, shoulders, and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 4 to 40 acres in size.

Map Unit Composition

Major Components
Rawsonville, very rocky, very bouldery: 45 percent
Hogback, very rocky, very bouldery: 30 percent

Inclusions
Ampersand: 5 percent
Knob Lock: 5 percent
Mundalite: 5 percent
Tunbridge: 4 percent
Lyman: 3 percent
Rock outcrop: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Ampersand, Knob Lock, Mundalite, Tunbridge, and Lyman soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Ampersand soils are on small depressions and drainageways. Knob Lock, Mundalite, Tunbridge, and Lyman soils occupy similar positions, but Knob Lock soils are shallow to very shallow and are organic, Mundalite soils are very deep, and Tunbridge and Lyman soils have less organic matter in the subsoil. Included areas can occupy about 25 percent of this unit.

0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
4 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
6 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture
- Erosion control is needed when pastures are renovated.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations caused by moderately deep and shallow soils.

- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations due to very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations due to very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

Tunbridge: 3 percent
Unnamed: 1 percent

The Knob Lock, Mundalite, Tunbridge, and Lyman soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Knob Lock, Mundalite, Tunbridge, and Lyman soils occupy similar positions, but Knob Lock soils are shallow to very shallow and are organic; Mundalite soils are very deep; and Tunbridge and Lyman soils have less organic matter in the subsoil. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
    Rawsonville, very rocky, very bouldery: no
    Hogback, very rocky, very bouldery: no
Hydrologic group:
    Rawsonville, very rocky, very bouldery: B
    Hogback, very rocky, very bouldery: D

Soil Properties and Qualities

Rawsonville, very rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
- 2 to 3 inches: extremely acid to strongly acid (3.5 to 5.5)
- 3 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
- 4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
- 5 to 11 inches: extremely acid to strongly acid (3.5 to 5.5)
- 11 to 20 inches: extremely acid to strongly acid (3.5 to 5.5)
- 20 to 25 inches: extremely acid to strongly acid (3.5 to 5.5)
- 25 inches, bedrock

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 5 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 11 to 20 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 20 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 25 inches, bedrock

Hogback, very rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low to moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
- 3 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
- 4 to 6 inches: extremely acid to strongly acid (3.5 to 5.5)
- 6 to 14 inches: extremely acid to strongly acid (3.5 to 5.5)
- 14 inches, bedrock

Permeability:
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 4 to 6 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 6 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 14 inches, bedrock

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture

- These soils are generally not recommended for pasture.

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations due to moderately deep and shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations due to very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and re-seeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to moderately deep soils. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

RmA—Rippowam fine sandy loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and poorly drained. It is on flood plains in the Champlain Valley. Areas range from 3 to 270 acres in size.

Map Unit Composition

Major Components
Rippowam: 85 percent

Inclusions
Pootatuck: 5 percent
Unnamed: 4 percent
Fluvaquents-Udifluvents: 3 percent
Gougeville: 3 percent

The moderately well drained Pootatuck, somewhat poorly drained and well drained Fluvaquents-Udifluvents, and Gougeville soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained, loamy flood plain soils. Pootatuck soils occupy higher positions. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Gougeville soils occupy similar positions, but are sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 4w
Hydric soil rating:
  Rippowam: yes
Hydrologic group:
  Rippowam: A/D

Soil Properties and Qualities

Rippowam
Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches

Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent
Flooding: frequent
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: flood plains
Parent material: loamy alluvium derived from igneous and sedimentary rock
Reaction (pH):
  0 to 2 inches: very strongly acid to neutral (4.5 to 7.3)
  2 to 11 inches: very strongly acid to neutral (4.5 to 7.3)
  11 to 21 inches: very strongly acid to neutral (4.5 to 7.3)
  21 to 29 inches: very strongly acid to neutral (4.5 to 7.3)
  29 to 36 inches: very strongly acid to neutral (4.5 to 7.3)
  36 to 43 inches: very strongly acid to neutral (4.5 to 7.3)
  43 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  2 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  11 to 21 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  21 to 29 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  29 to 36 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  36 to 43 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  43 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are poorly suited to cultivated crops due to the seasonal high water table.
- Flooding may delay planting or damage crops in some years.
- The root system of some deep-rooted crops may be damaged by frost action.

Pasture
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality

limitations due to wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The RmA map unit is a taxadjunct to the Rippowam series because the pedon qualifies as not having a Cambic horizon. The classification of the taxadjunct is Coarse-loamy, mixed, superactive, nonacid, mesic Aeric Fluvaquents. This is the former classification of the Rippowam series prior to changes regarding the Cambic horizon in Soil Taxonomy in 1999. The present Rippowam classification is Coarse-loamy, mixed, superactive, nonacid, mesic Fluvaquentic Endoaquepts. This should not significantly affect use and management on a local basis for most purposes.

RpF—Rock outcrop-Knob Lock-Lyman complex, 35 to 60 percent slopes, very bouldery

Setting

This map unit consists of areas of exposed bedrock and soils that are loamy and organic, shallow to very shallow, very steep, and well drained to excessively drained.

It is on backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 4 to 660 acres in size.

Map Unit Composition

Major Components
Rock outcrop, very bouldery: 40 percent
Knob Lock, very rocky, very bouldery: 30 percent
Lyman, very rocky, very bouldery: 20 percent

Inclusions
Tunbridge: 3 percent
Becket: 2 percent
Hogback: 2 percent
Hermon: 1 percent
Monadnock: 1 percent
Unnamed: 1 percent

The Tunbridge, Becket, Hogback, Monadnock, and somewhat excessively drained Hermon soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Tunbridge, Hogback, Becket, Monadnock, and Hermon soils occupy similar positions, but Tunbridge soils are moderately deep to bedrock; Hogback soils have more organic matter than Lyman soils; Becket, Monadnock, and Hermon soils are very deep to bedrock; Monadnock soils are loamy over sandy or gravelly; and Hermon soils are sandy and gravelly. Included areas can occupy about 10 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:
- Rock outcrop, very bouldery: no
- Knob Lock, very rocky, very bouldery: no
- Lyman, very rocky, very bouldery: no

Hydrologic group:
- Rock outcrop, very bouldery: unranked
- Knob Lock, very rocky, very bouldery: D
- Lyman, very rocky, very bouldery: D

Rock outcrop, very bouldery
Characteristics not defined for this component.

Knob Lock, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 1 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very high
Landform: glaciated hillside or mountainsides
Parent material: non-saturated organic material over loamy till derived from gneiss
Reaction (pH):
- 0 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
- 3 to 7 inches: ultra acid or extremely acid (1.8 to 4.4)
- 7 to 9 inches: extremely acid or very strongly acid (3.5 to 5.0)
- 9 inches, bedrock

Permeability:
- 0 to 3 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 3 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 7 to 9 inches: moderate to very rapid (0.6 to 100 inches/hour)
- 9 inches, bedrock

Lyman, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
- 0 to 0 inches: ultra acid or extremely acid (1.8 to 4.4)
- 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
- 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
- 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
- 3 to 9 inches: extremely acid to moderately acid (3.5 to 6.0)
- 9 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
- 13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
- 18 inches, bedrock

Permeability:
- 0 to 0 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
- 1 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 3 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.

- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- Because of the depth to bedrock, these soils are very limited as a site for septic tank absorption fields. Use of alternative systems may be possible in areas of deeper soil inclusions.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

RsA—Roundabout silt loam, 0 to 3 percent slopes

Setting

This soil is silty, very deep, nearly level, and somewhat poorly drained. It is on footslopes of glacial valley walls in the Adirondack Upland. Areas range from 3 to 90 acres in size.

Map Unit Composition

Major Components
Roundabout: 85 percent

Inclusions
Nicholville: 5 percent
Unnamed: 4 percent
Hailesboro: 3 percent
Naumburg: 2 percent
Wegatchie: 1 percent

The moderately well drained Nicholville, Hailesboro, Naumburg, and poorly drained Wegatchie soils may be included in areas of this map unit. Also included are small areas of poorly drained silty soils. Nicholville soils occupy higher positions. Hailesboro and Naumburg soils occupy similar positions, but Hailesboro soils are silty and clayey; and Naumburg soils are sandy. Wegatchie soils are on small depressions and drainageways, and are silty and clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
  Roundabout: no
Hydrologic group:
  Roundabout: A/D

Soil Properties and Qualities

Roundabout
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: glacial-valley walls
Parent material: silty glaciolacustrine deposits derived from gneiss
Reaction (pH):
  0 to 11 inches: very strongly acid to slightly acid (4.5 to 6.5)
  11 to 19 inches: very strongly acid to slightly acid (4.5 to 6.5)
  19 to 28 inches: very strongly acid to slightly acid (4.5 to 6.5)
  28 to 42 inches: moderately acid to neutral (5.6 to 7.3)
  42 to 72 inches: moderately acid to neutral (5.6 to 7.3)
Permeability:
  0 to 11 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  11 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  19 to 28 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  28 to 42 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  42 to 72 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

Use and Management

Cropland
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

RuA—Rumney loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and poorly drained. It is on flood plains in the Adirondack Upland. Areas range from 4 to 225 acres in size.

Map Unit Composition

Major Components
Rumney: 85 percent

Inclusions
Burnt Vly: 3 percent
Medomak: 3 percent
Podunk: 3 percent
Charles: 2 percent
Fluvaquents-Udifluvents: 2 percent
Searsport: 2 percent

The very poorly drained Burnt Vly, Medomak, Searsport, moderately well drained Podunk, Charles, and somewhat poorly drained and well drained Fluvaquents-Udifluvents soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained, loamy flood plain soils. Burnt Vly, Medomak, and Searsport soils occupy lower positions; Burnt Vly soils are mucky; Medomak soils are silty; and Searsport soils are sandy. Podunk soils occupy higher positions. Charles soils occupy similar positions, but are silty. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are poorly suited to cultivated crops due to the seasonal high water table.
- Flooding may delay planting or damage crops in some years.
- The root system of some deep-rooted crops may be damaged by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.

- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

RyA—Rumney-Burnt Vly complex, 0 to 3 percent slopes

Setting

These soils are loamy and mucky, very deep, nearly level, and poorly drained to very poorly drained. They are on flood plains in the Adirondack Upland. Areas range from 5 to 150 acres in size.

Map Unit Composition

Major Components

Rumney: 45 percent
Burnt Vly: 30 percent

Inclusions

Fluvaquents-Udifluvents: 5 percent
Pleasant Lake: 5 percent
Podunk: 5 percent
Tahawus: 5 percent
Wonsqueak: 5 percent

The somewhat poorly and well drained Fluvaquents-Udifluvents, moderately well drained Podunk, Pleasant Lake, Tahawus, and Wonsqueak soils may be included in areas of this map unit. Also included are small areas of somewhat poorly drained loamy flood plain soils. Fluvaquents-Udifluvents soils occupy positions directly adjacent to the stream channel. Podunk soils occupy higher positions. Pleasant Lake, Tahawus, and Wonsqueak soils occupy similar positions, but Pleasant Lake soils are greater than 51 inches deep to mineral soil material; Tahawus soils are sandy and underlain by till; and Wonsqueak soils have a higher pH than Burnt Vly soils. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 4w
Hydric soil rating:
Rumney: yes
Burnt Vly: yes
Hydrologic group:
Rumney: B/D
Burnt Vly: B/D

Soil Properties and Qualities

Rumney

Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
Water table kind: apparent
Flooding: frequent
Available water capacity: moderate
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: flood plains
Parent material: loamy alluvium derived from gneiss
Reaction (pH):
0 to 7 inches: very strongly acid to neutral (4.5 to 7.3)
7 to 12 inches: very strongly acid to neutral (4.5 to 7.3)
12 to 19 inches: very strongly acid to neutral (4.5 to 7.3)
19 to 30 inches: very strongly acid to neutral (4.5 to 7.3)
30 to 33 inches: very strongly acid to neutral (4.5 to 7.3)
33 to 48 inches: very strongly acid to neutral (4.5 to 7.3)
48 to 54 inches: very strongly acid to neutral (4.5 to 7.3)
54 to 72 inches: very strongly acid to neutral (4.5 to 7.3)

Permeability:
0 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
7 to 12 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
12 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
19 to 30 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
30 to 33 inches: moderately rapid to very rapid (2 to 100 inches/hour)
33 to 48 inches: moderately rapid to very rapid (2 to 100 inches/hour)
48 to 54 inches: moderately rapid to very rapid (2 to 100 inches/hour)
54 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Burnt Vly
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 inches
Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: flood plains
Parent material: organic material over sandy glaciofluvial deposits
Reaction (pH):
0 to 10 inches: ultra acid to very strongly acid (1.8 to 4.5)
10 to 15 inches: ultra acid to very strongly acid (1.8 to 4.5)
15 to 24 inches: ultra acid to very strongly acid (1.8 to 4.5)
24 to 34 inches: ultra acid to very strongly acid (1.8 to 4.5)
34 to 56 inches: extremely acid to slightly acid (3.5 to 6.5)
56 to 72 inches: extremely acid to slightly acid (3.5 to 6.5)
Permeability:
0 to 10 inches: moderately slow to rapid (0.2 to 20 inches/hour)
10 to 15 inches: moderately slow to rapid (0.2 to 20 inches/hour)
15 to 24 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
24 to 34 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
34 to 56 inches: moderate to very rapid (0.6 to 100 inches/hour)
56 to 72 inches: moderate to very rapid (0.6 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are poorly suited to cultivated crops due to the seasonal high water table.
- Flooding may delay planting or damage crops in some years.
- The root system of some deep-rooted crops may be damaged by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.
- These soils are generally unsuited to cultivated crops due to ponding in some areas.

Pasture
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.

- Sediment left on forage plants after a flood event may reduce palatability and forage intake by the grazing animal.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.
- These soils are poorly suited to pasture due to ponding in some areas.

Woodland

- Avoiding construction of haul roads in frequently flooded areas is recommended.
- Avoiding construction of log landings on frequently flooded soils is recommended.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Potential for flooding severely limits the capacity of these soils to bear a load without movement. Flooding may result in costly physical damage to buildings.
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields

- Probable flooding in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Rapidly moving floodwaters may damage some components of septic systems.
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- Flooding limits the use of these soils for local roads and streets. Special design of roads and bridges is necessary.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.

SeA—Searsport peat, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and very poorly drained. It is on toeslopes of deltas, outwash plains, and stream terraces in the Adirondack Upland. Areas range from 3 to 80 acres in size.

Map Unit Composition

Major Components
Searsport: 85 percent

Inclusions
Naumburg: 5 percent
Burnt Vly: 4 percent
Wegatchie: 3 percent
Tahawus: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Naumburg, Burnt Vly, Wegatchie, and Tahawus soils may be included in areas of this map unit. Also included are small areas of poorly drained sandy soils. Naumburg soils occupy higher positions. Burnt Vly, Wegatchie, and Tahawus soils occupy similar positions, but Burnt Vly soils are mucky, Wegatchie soils are silty and clayey, and Tahawus soils are underlain by till. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
    Searsport: yes
Hydrologic group:
    Searsport: B/D

Soil Properties and Qualities

Searsport
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches

  22 to 32 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  32 to 40 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  40 to 48 inches: moderately rapid to very rapid (2 to 100 inches/hour)
  48 to 54 inches: moderate to very rapid (0.6 to 100 inches/hour)
  54 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads due to wetness.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Maintaining a vegetative cover or spreading slash over exposed soil areas will help overcome harvest equipment operability limitations due to sandy surfaces.

- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.

Septic Tank Absorption Fields

- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets

- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The SeA and 367A map units have components with textures below 40 inches that are finer than typical for the range of the Searsport series. This should not significantly affect use and management on a local basis for most purposes.

SkB—Skerry loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on footslopes and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 140 acres in size.

Map Unit Composition

Major Components
Skerry: 85 percent

Inclusions
Adirondack: 5 percent
Becket: 5 percent
Sunapee: 3 percent
Unnamed: 2 percent

The somewhat poorly drained Adirondack, well drained Becket, and Sunapee soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Adirondack soils occupy slightly lower positions. Becket soils occupy higher positions. Sunapee soils occupy similar positions but lack the dense substratum. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2e
Hydric soil rating:
  Skerry: no
Hydrologic group:
  Skerry: B/D

Soil Properties and Qualities

Skerry
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 38 inches to densic material
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: perched
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 4 inches: extremely acid to slightly acid (3.5 to 6.5)
  4 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 15 inches: extremely acid to slightly acid (3.5 to 6.5)
  15 to 26 inches: extremely acid to slightly acid (3.5 to 6.5)
  26 to 38 inches: extremely acid to slightly acid (3.5 to 6.5)
  38 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
  2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  9 to 15 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  15 to 26 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  26 to 38 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  38 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland

- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

SnB—Sunapee fine sandy loam, 3 to 8 percent slopes, very bouldery

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on footslopes and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 155 acres in size.

Map Unit Composition

Major Components
Sunapee, very bouldery: 85 percent

Inclusions
Monadnock: 5 percent
Adirondack: 4 percent
Fernlake: 3 percent
Skerry: 3 percent

The well drained Monadnock, somewhat poorly drained Adirondack, somewhat excessively drained Fernlake, and Skerry soils may be included in areas of this map unit. Monadnock and Fernlake soils occupy higher positions, and Fernlake soils are sandy. Adirondack soils occupy slightly lower positions and have a dense substratum. Skerry soils occupy similar positions, but have a dense substratum. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Sunapee, very bouldery: no
Hydrologic group:
  Sunapee, very bouldery: B

Soil Properties and Qualities

Sunapee, very bouldery
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches

Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
  4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
  5 to 7 inches: extremely acid to strongly acid (3.5 to 5.5)
  7 to 14 inches: extremely acid to strongly acid (3.5 to 5.5)
  14 to 19 inches: extremely acid to strongly acid (3.5 to 5.5)
  19 to 31 inches: extremely acid to strongly acid (3.5 to 5.5)
  31 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  7 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  14 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  19 to 31 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  31 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture

- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard. Consult the Water Features table for months of seasonal saturation.

- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

SpB—Sunapee fine sandy loam, 3 to 8 percent slopes

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on footslopes and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 75 acres in size.

Map Unit Composition

Major Components
Sunapee: 85 percent

Inclusions
Monadnock: 5 percent
Adirondack: 4 percent

Fernlake: 3 percent
Skerry: 3 percent

The well drained Monadnock, somewhat poorly drained Adirondack, somewhat excessively drained Fernlake, and Skerry soils may be included in areas of this map unit. Also included are areas that lack a spodic horizon. Monadnock and Fernlake soils occupy higher positions, and Fernlake soils are sandy. Adirondack soils occupy slightly lower positions, and have a dense substratum. Skerry soils occupy similar positions, but have a dense substratum. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland
Land capability classification: 2w
Hydric soil rating:
  Sunapee: no
Hydrologic group:
  Sunapee: B

Soil Properties and Qualities

Sunapee
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: low
Landform: glaciated hillside or mountainsides
Parent material: loamy ablation till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 4 inches: extremely acid to strongly acid (3.5 to 5.5)
  4 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
  5 to 7 inches: extremely acid to strongly acid (3.5 to 5.5)
  7 to 14 inches: extremely acid to strongly acid (3.5 to 5.5)
  14 to 19 inches: extremely acid to strongly acid (3.5 to 5.5)
  19 to 31 inches: extremely acid to strongly acid (3.5 to 5.5)
  31 to 72 inches: extremely acid to moderately acid (3.5 to 6.0)
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  5 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  7 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  14 to 19 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  19 to 31 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  31 to 72 inches: moderately rapid or rapid (2 to 20 inches/hour)

Use and Management

Cropland
- These soils are among those soils in the county best suited for growing cultivated crops and meet the criteria for prime farmland.

- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard. Consult the Water Features table for months of seasonal saturation.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- Excessive rates of water movement or seepage through parts of the soil substrata may limit the proper treatment of the effluent from septic systems in some areas. Installing distribution lines well above the depth of the coarse-textured substrata can help provide filter capacity.
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

SrB—Skerry loam, 3 to 8 percent slopes, very bouldery

Setting

This soil is loamy, very deep, gently sloping, and moderately well drained. It is on footslopes and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 3 to 230 acres in size.

Map Unit Composition

Major Components
Skerry, very bouldery: 85 percent

Inclusions
Adirondack: 5 percent
Becket: 5 percent
Sunapee: 3 percent
Unnamed: 2 percent

The somewhat poorly drained Adirondack, well drained Becket, and Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adirondack soils occupy slightly lower positions. Becket soils occupy higher positions. Sunapee soils occupy similar positions but lack the dense substratum. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Skerry, very bouldery: no
Hydrologic group:
  Skerry, very bouldery: B/D

Soil Properties and Qualities

Skerry, very bouldery
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 20 to 38 inches to densic material
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: perched
Flooding: none
Available water capacity: high
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: medium
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from gneiss
Reaction (pH):
  0 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
  2 to 4 inches: extremely acid to slightly acid (3.5 to 6.5)
  4 to 5 inches: extremely acid to slightly acid (3.5 to 6.5)
  5 to 9 inches: extremely acid to slightly acid (3.5 to 6.5)
  9 to 15 inches: extremely acid to slightly acid (3.5 to 6.5)
  15 to 26 inches: extremely acid to slightly acid (3.5 to 6.5)
  26 to 38 inches: extremely acid to slightly acid (3.5 to 6.5)
  38 to 72 inches: very strongly acid to neutral (4.5 to 7.3)

Permeability:
- 0 to 2 inches: moderately rapid or rapid (2 to 20 inches/hour)
- 2 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 4 to 5 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 5 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 9 to 15 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 15 to 26 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 26 to 38 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 38 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations due to very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.

- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

SrC—Skerry loam, 8 to 15 percent slopes, very bouldery

Setting

This soil is loamy, very deep, strongly sloping, and moderately well drained. It is on footslopes and backslopes of glaciated hillsides and mountainsides in the Adirondack Upland. Areas range from 4 to 200 acres in size.

Map Unit Composition

Major Components
Skerry, very bouldery: 85 percent

Inclusions
Adirondack: 5 percent
Becket: 5 percent
Sunapee: 3 percent
Unnamed: 2 percent

The somewhat poorly drained Adirondack, well drained Becket, and Sunapee soils may be included in areas of this map unit. Also included are areas that lack a very bouldery surface. Adirondack soils occupy slightly lower positions. Becket soils occupy higher positions. Sunapee soils occupy similar positions but lack the dense substratum. Included areas can occupy about 15 percent of this unit.

    15 to 26 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    26 to 38 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
    38 to 72 inches: slow or moderately slow (0.06 to 0.6 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of surface boulders and stones.

Pasture
- Erosion control is needed when pastures are renovated.
- Large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations caused by very bouldery or extremely stony surface conditions.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.

- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

StA—Stafford fine sandy loam, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and somewhat poorly drained. It is on footslopes and toeslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 135 acres in size.

Map Unit Composition

Major Components
Stafford: 85 percent

Inclusions
Deerfield: 5 percent
Gougeville: 4 percent
Tonawanda: 3 percent
Cosad: 2 percent
Claverack: 1 percent

The moderately well drained Deerfield and Claverack, poorly drained Gougeville, Tonawanda, and Cosad soils may be included in areas of this map unit. Deerfield and Claverack soils occupy higher positions, and Claverack soils are sandy over clayey. Gougeville soils occupy slightly lower positions. Tonawanda and Cosad soils occupy similar positions, but Tonawanda soils are silty, and Cosad soils are sandy over clayey. Included areas make up about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 3w
Hydric soil rating:
  Stafford: no
Hydrologic group:
  Stafford: A/D

Soil Properties and Qualities

Stafford
Drainage class: somewhat poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
  Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 10 inches: very strongly acid to neutral (4.5 to 7.3)
  10 to 20 inches: extremely acid to slightly acid (3.5 to 6.5)
  20 to 32 inches: extremely acid to neutral (3.5 to 7.3)
  32 to 72 inches: strongly acid to neutral (5.1 to 7.3)
Permeability:
  0 to 10 inches: moderately rapid or rapid (2 to 20 inches/hour)
  10 to 20 inches: rapid (6 to 20 inches/hour)
  20 to 32 inches: rapid (6 to 20 inches/hour)
  32 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.

- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The StA map unit has reaction in the lower part that is slightly out of the range of the Stafford series. This should not significantly affect use and management on a local basis for most purposes.

SuA—Sun silt loam, 0 to 3 percent slopes

Setting

This soil is loamy, very deep, nearly level, and poorly drained. It is on toeslopes of till plains and drumlinoid ridges in the Champlain Valley. Areas range from 3 to 35 acres in size.

Map Unit Composition

Major Components
Sun: 85 percent

Inclusions
Massena: 5 percent
Whallonsburg: 4 percent
Covington: 3 percent
Unnamed: 3 percent

The somewhat poorly drained Massena, Whallonsburg, and Covington soils may be included in areas of this map unit. Also included are areas that have a very stony surface. Massena soils occupy higher positions. Whallonsburg soils occupy lower positions, and are mucky over clayey. Covington soils occupy similar positions, but are clayey. Included areas make up about 15 percent of this unit.

 15 to 25 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 25 to 40 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 40 to 54 inches: slow (0.06 to 0.2 inches/hour)
 54 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland

- These soils are poorly suited to cultivated crops due to the seasonal high water table.
- The root system of some deep-rooted crops may be damaged by frost action.

Pasture

- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland

- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads due to wetness.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields

- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The somewhat limited depth to dense material reduces the filtering capacity of these soils and may greatly increase the difficulty of proper installation of the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The Sun SuA map unit has a firm C horizon below the Cd that is not within the range of the Sun series. This should not significantly affect the use and management on a local basis.

TaA—Tahawus peat, 0 to 5 percent slopes, very bouldery

Setting

This soil is sandy, very deep, nearly level, and very poorly drained. It is on toeslopes of till plains in the Adirondack Upland. Areas range from 3 to 165 acres in size.

Map Unit Composition

Major Components
Tahawus, very bouldery: 85 percent

Inclusions
Adirondack: 5 percent
Burnt Vly: 5 percent
Unnamed: 3 percent
Sunapee: 2 percent

The somewhat poorly drained Adirondack, Burnt Vly, and moderately well drained Sunapee soils may be included in areas of this map unit. Also included are areas that have an extremely bouldery surface. Adirondack and Sunapee soils occupy higher positions, both are loamy, and Adirondack soils have a dense substratum. Burnt Vly soils occupy similar positions, but are mucky over sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Tahawus, very bouldery: yes
Hydrologic group:
  Tahawus, very bouldery: B/D

Soil Properties and Qualities

Tahawus, very bouldery
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated till plains
Parent material: sandy till derived from gneiss
Reaction (pH):
  0 to 2 inches: extremely acid to strongly acid (3.5 to 5.5)
  2 to 5 inches: extremely acid to strongly acid (3.5 to 5.5)
  5 to 9 inches: extremely acid to strongly acid (3.5 to 5.5)

9 to 17 inches: very strongly acid to slightly acid (4.5 to 6.5)
17 to 24 inches: moderately acid to neutral (5.6 to 7.3)
24 to 72 inches: moderately acid to neutral (5.6 to 7.3)

Permeability:
0 to 2 inches: moderately slow to rapid (0.2 to 20 inches/hour)
2 to 5 inches: moderately slow to rapid (0.2 to 20 inches/hour)
5 to 9 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
9 to 17 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
17 to 24 inches: moderately rapid to very rapid (2 to 100 inches/hour)
24 to 72 inches: moderately rapid to very rapid (2 to 100 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets

- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

TeA—Typic Endoaquolls, nearly level, very stony

Setting

This soil is loamy, very deep, nearly level, and poorly drained. It is on toeslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 3 to 85 acres in size.

Map Unit Composition

Major Components
Typic Endoaquolls, very stony: 85 percent

Inclusions
Wonsqueak: 4 percent
Malone: 3 percent
Wegatchie: 3 percent
Searsport: 2 percent
Tahawus: 2 percent
Unnamed: 1 percent

The Wonsqueak, somewhat poorly drained Malone, poorly drained Wegatchie, Searsport, and Tahawus soils may be included in areas of this map unit. Also included are areas that have an extremely stony surface. Wonsqueak, Searsport, and Tahawus soils occupy slightly lower positions, Wonsqueak soils are mucky over loamy, Searsport and Tahawus soils are sandy, and Searsport soils are underlain by outwash. Malone soils occupy higher positions. Wegatchie soils occupy similar positions but are silty and clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Typic Endoaquolls, very stony: yes
Hydrologic group:
  Typic Endoaquolls, very stony: B/D

Soil Properties and Qualities

Typic Endoaquolls, very stony
Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent
Flooding: none

Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very stony
Landform: glaciated hillside or mountainsides
Parent material: loamy lodgment till derived from igneous and sedimentary rock
Reaction (pH):
  0 to 10 inches: slightly acid or neutral (6.1 to 7.3)
  10 to 15 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  15 to 24 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  24 to 72 inches: slightly acid to moderately alkaline (6.1 to 8.4)
Permeability:
  0 to 10 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  10 to 15 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  15 to 24 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  24 to 72 inches: moderately slow or moderate (0.2 to 2 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained and very poorly drained soils and areas of soils that are subject to ponding should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

Correlation Note: The TeA map unit is at the Taxon above Family. It was intended to be the Runeberg series. While it fits the classification of the Runeberg series, the properties of the Minnesota based series do not fit the Essex County climate, elevation, water table, and permeability.

ToA—Tonawanda silt loam, 0 to 3 percent slopes

Setting

These soils are silty, very deep, nearly level, and somewhat poorly drained. They are on footslopes of lake plains in the Champlain Valley. Areas range from 3 to 135 acres in size.

Map Unit Composition

Major Components
Tonawanda: 85 percent

Inclusions
Stafford: 5 percent
Niagara: 4 percent
Gougeville: 3 percent
Hartland: 2 percent
Unnamed: 1 percent

The Stafford, Niagara, poorly drained Gougeville, and well drained Hartland soils may be included in areas of this map unit. Also included are small areas of moderately well drained silty soils. Dunkirk, Stafford and Niagara soils occupy similar positions, but Stafford soils are sandy, and Niagara soils are silty and clayey. Gougeville soils occupy lower positions and are sandy. Hartland soils occupy higher positions. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: prime farmland if drained
Land capability classification: 3w
Hydric soil rating:
    Tonawanda: no
Hydrologic group:
    Tonawanda: A/D

Soil Properties and Qualities

Tonawanda
Drainage class: somewhat poorly drained

Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 6 to 18 inches
Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: very high
Landform: lake plains
Parent material: silty glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
0 to 9 inches: strongly acid to neutral (5.1 to 7.3)
9 to 14 inches: strongly acid to neutral (5.1 to 7.3)
14 to 22 inches: strongly acid to neutral (5.1 to 7.3)
22 to 72 inches: moderately acid to slightly alkaline (5.6 to 7.8)
Permeability:
0 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
9 to 14 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
14 to 22 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
22 to 72 inches: moderate or moderately rapid (0.6 to 6 inches/hour)

Use and Management

Cropland
- Systematic subsurface drainage may extend the period of planting and harvesting of crops.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.

- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to seasonal wetness. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

TuC—Tunbridge-Lyman complex, 8 to 15 percent slopes, very rocky, very bouldery

Setting

These soils are loamy, moderately deep and shallow, strongly sloping, and well drained. They are on summits, shoulders, and backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 3 to 165 acres in size.

Map Unit Composition

Major Components
Tunbridge, very rocky, very bouldery: 45 percent
Lyman, very rocky, very bouldery: 30 percent

Inclusions
Becket: 5 percent
Monadnock: 5 percent
Rock outcrop: 5 percent

Skerry: 5 percent
Knob Lock: 3 percent
Rawsonville: 2 percent

The Becket, Monadnock, Knob Lock, Rawsonville, and moderately well drained Skerry soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Becket, Monadnock, Knob Lock and Rawsonville soils occupy similar positions, but Becket and Monadnock soils are very deep to bedrock and Monadnock soils are loamy over sandy or gravelly, Knob Lock soils are organic and very shallow to shallow, and Rawsonville soils have more organic matter in the subsoil. Skerry soils are on small depressions or drainageways, and are very deep to bedrock. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6s
Hydric soil rating:
  Tunbridge, very rocky, very bouldery: no
  Lyman, very rocky, very bouldery: no
Hydrologic group:
  Tunbridge, very rocky, very bouldery: ?
  Lyman, very rocky, very bouldery: D

Soil Properties and Qualities

Tunbridge, very rocky, very bouldery
Drainage class: well drained
Depth to bedrock: 20 to 40 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
  0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
  1 to 3 inches: ultra acid or extremely acid (1.8 to 4.4)
  3 to 4 inches: extremely acid to moderately acid (3.5 to 6.0)
  4 to 7 inches: extremely acid to moderately acid (3.5 to 6.0)
  7 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
  13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
  18 to 27 inches: strongly acid to slightly acid (5.1 to 6.5)
  27 inches, bedrock
Permeability:
  0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
  1 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  3 to 4 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  4 to 7 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  7 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  18 to 27 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
  27 inches, bedrock

Lyman, very rocky, very bouldery
Drainage class: somewhat excessively drained
Depth to bedrock: 10 to 20 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: low
Potential frost action: moderate
Shrink-swell potential: low
Surface runoff potential: very high
Surface fragment cover: very bouldery
Landform: glaciated hillside or mountainsides
Parent material: loamy till derived from gneiss
Reaction (pH):
 0 to 0 inches: ultra acid or extremely acid (1.8 to 4.4)
 0 to 1 inch: ultra acid or extremely acid (1.8 to 4.4)
 1 to 2 inches: ultra acid or extremely acid (1.8 to 4.4)
 2 to 3 inches: extremely acid to moderately acid (3.5 to 6.0)
 3 to 9 inches: extremely acid to moderately acid (3.5 to 6.0)
 9 to 13 inches: extremely acid to moderately acid (3.5 to 6.0)
 13 to 18 inches: extremely acid to moderately acid (3.5 to 6.0)
 18 inches, bedrock
Permeability:
 0 to 0 inches: moderately rapid or rapid (2 to 20 inches/hour)
 0 to 1 inch: moderately rapid or rapid (2 to 20 inches/hour)
 1 to 2 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 2 to 3 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 3 to 9 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 9 to 13 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
 18 inches, bedrock

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture
- Erosion control is needed when pastures are renovated.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Locating haul roads on soils that are deeper to bedrock or maintaining minimal grades to reduce cut and fill on these soils will help overcome construction limitations due to moderately deep and shallow soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Locating log landings in areas with fewer surface boulders or stones will help overcome construction and operational limitations due to very bouldery or extremely stony surface conditions.

- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

TuD—Tunbridge-Lyman complex, 15 to 35 percent slopes, very rocky, very bouldery

Setting

These soils are loamy, moderately deep and shallow, moderately steep and steep, and well drained. They are on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland (fig. 23). Areas range from 3 to 385 acres in size.

Figure 23.—This photo illustrates the depth to bedrock in Tunbridge-Lyman map units. The moderately deep Tunbridge soils lie to the right and under the tile spade. Depth to bedrock thins out to the left of the spade where the shallow Lyman soils lie. Timber production is moderate on these soils for White Pine, Red Pine, and Northern Red Oak. Native fertility is low, and trees may suffer moisture stress in dry years on shallower soils. Special care should be taken during timber harvesting operations to protect bedrock controlled soils from damage and accelerated erosion. These soils have severe limitations for residential development and local roads and streets because of the shallow depths to bedrock.

Map Unit Composition

Major Components

Tunbridge, very rocky, very bouldery: 45 percent
Lyman, very rocky, very bouldery: 30 percent

Inclusions

Knob Lock: 7 percent
Rock outcrop: 7 percent
Becket: 3 percent
Monadnock: 3 percent

Rawsonville: 3 percent
Nehasne: 2 percent

The Knob Lock, Becket, Monadnock, Rawsonville, and Nehasne soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Knob Lock, Becket, Monadnock, Rawsonville, and Nehasne soils occupy similar positions, but Knob Lock soils are organic and very shallow to shallow, Becket and Monadnock soils are very deep to bedrock and Monadnock soils are loamy over sandy or gravelly, Rawsonville soils have more organic matter in the subsoil, and Nehasne soils lack a spodic horizon and have a higher pH. Included areas can occupy about 25 percent of this unit.

- 13 to 18 inches: moderate or moderately rapid (0.6 to 6 inches/hour)
- 18 inches, bedrock

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of the rock outcrops.

Pasture

- The slope may restrict the use of most farm equipment.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.
- Rock outcrops and large rock fragments on the surface may restrict the operation of some farm machinery during pasture renovation.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads due to steep slopes.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by moderately deep and shallow soils.
- Employing larger, more powerful machinery during construction and locating haul roads in areas with fewer surface boulders or stones will help overcome construction limitations caused by very bouldery or extremely stony surface conditions.
- Constructing log landings on less sloping soils is recommended.

- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

TuF—Tunbridge-Lyman complex, 35 to 60 percent slopes, very rocky, very bouldery

Setting

These soils are loamy, moderately deep and shallow, very steep, and well drained. They are on backslopes of glaciated hillsides or mountainsides in the Adirondack Upland. Areas range from 3 to 355 acres in size.

Map Unit Composition

Major Components
Tunbridge, very rocky, very bouldery: 45 percent
Lyman, very rocky, very bouldery: 30 percent

Inclusions
Rock outcrop: 9 percent
Knob Lock: 8 percent
Monadnock: 3 percent
Rawsonville: 3 percent
Becket: 2 percent

The Knob Lock, Monadnock, Rawsonville, and Becket soils may be included in areas of this map unit. Also included are areas of very shallow mineral soils. Knob Lock, Monadnock, Rawsonville, and Becket soils occupy similar positions, but Knob Lock soils are organic and are very shallow to shallow; Becket and Monadnock soils are very deep to bedrock and Monadnock soils are loamy over sandy or gravelly; and Rawsonville soils have more organic matter in the subsoil. Included areas can occupy about 25 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 7s
Hydric soil rating:

18 inches, bedrock

Use and Management

Cropland

- These soils are generally unsuited to use as cropland because of the slope, the erosion hazard, and the rock outcrops.

Pasture

- These soils are generally not recommended for pasture.

Woodland

- Avoiding construction of haul roads on slopes exceeding 35 percent is recommended.
- Locating haul roads on soils that are deeper to bedrock will help overcome construction limitations caused by moderately deep and shallow soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by very steep slopes.
- Careful planning and preparation of skid trails and operation of large rubber tired skidding equipment may help overcome harvest equipment operability limitations caused by very bouldery or extremely stony surface conditions.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to shallow soils. Buffer systems may be useful in high risk topographic areas. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The depth to bedrock and hardness of the bedrock greatly reduce the ease of excavation and increase the difficulty of constructing foundations and installing utilities. Some excavation may be possible in inclusions of deeper soils.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The somewhat limited depth to bedrock reduces the filtering capacity of these soils and greatly increases the difficulty of proper installation of the effluent distribution lines. Some bedrock types have cracks and crevices that may allow inadequately treated effluent to enter and contaminate the groundwater.
- Large rock fragments on the surface may impede excavation, system installation, and traffic of heavy machinery. If surface rock fragments are removed, retaining the natural soil surface layer is particularly important where a restrictive soil feature limits the thickness of suitable soil material.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- Depth to hard bedrock limits site preparation such as shaping and grading and restricts installation of roads and streets. Blasting may be necessary.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

UlC—Udorthents, nearly level through strongly sloping

Setting

This map unit consists of disturbed areas that are made up of old abandoned industrial sites, closed landfills, borrow pits, or construction sites. These areas are usually reclaimed with native soil material and smoothed, but may contain or be underlain by refuse, construction and demolition debris, or other waste. They are relatively few in number and scattered throughout the county. Areas range from 3 to 125 acres in size.

Map Unit Composition

Major Components
Udorthents: 100 percent

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 8
Hydric soil rating:
  Udorthents: no
Hydrologic group:
  Udorthents: C

Soil Properties and Qualities

Udorthents
Drainage class: well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: variable
Potential frost action: variable
Shrink-swell potential: variable
Surface runoff potential: variable
Landform: anthropogenic terraces
Parent material: mine spoil, earthy fill, refuse
Reaction (pH):
  0 to 2 inches: strongly acid to moderately alkaline (5.1 to 8.4)
  2 to 21 inches: strongly acid to moderately alkaline (5.1 to 8.4)
  21 to 72 inches: strongly acid to moderately alkaline (5.1 to 8.4)
Permeability:
  0 to 2 inches: slow to rapid (0.06 to 20 inches/hour)
  2 to 21 inches: slow to rapid (0.06 to 20 inches/hour)
  21 to 72 inches: slow to rapid (0.06 to 20 inches/hour)

Use and Management

Cropland
- These areas are generally unsuited to use as cropland because of the uncertain nature of the parent material.

Pasture
- These areas are generally unsuited to use as pasture because of the uncertain nature of the parent material.

Woodland
- Some areas, with the exception of closed landfills, may be reclaimed for commercial woodland use. Onsite investigation is needed to determine tree species to plant, and various conservation practices to employ.

Development
- These areas are generally unsuited for most development purposes because of the uncertain nature of the parent material.

Local Roads and Streets
- Onsite investigation is needed to determine the suitability of these areas for local roads and streets because of the uncertain nature of the parent material.

UmF—Udorthents, mine spoil, nearly level through very steep

This map unit consists of small to large man-made hills adjacent to inactive open pit and shaft mining operations, and are made up of waste mining debris removed from the pits or shafts. The mine spoil is generally sandy, excessively drained, and can be extremely stony or bouldery. These areas may be reclaimed with non-native or local soil material and smoothed. Most of these areas are located in the towns of Newcomb and Moriah. Areas range from 3 to 635 acres in size.

Map Unit Composition

Major Components
Udorthents, mine spoil: 100 percent

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 8
Hydric soil rating:
  Udorthents, mine spoil: no
Hydrologic group:
  Udorthents, mine spoil: A

Soil Properties and Qualities

Udorthents, mine spoil
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: medium

Landform: anthropogenic terraces
Parent material: sandy and gravelly metal ore extraction mine spoil derived from gneiss
Reaction (pH):
0 to 5 inches: moderately acid to slightly alkaline (5.6 to 7.8)
5 to 9 inches: moderately acid to neutral (5.6 to 7.3)
9 to 72 inches: slightly acid to strongly alkaline (6.1 to 9.0)
Permeability:
0 to 5 inches: slow to moderate (0.06 to 2 inches/hour)
5 to 9 inches: slow to moderate (0.06 to 2 inches/hour)
9 to 72 inches: very rapid (20 to 100 inches/hour)

Use and Management

Cropland
- These areas are generally unsuited to use as cropland.

Pasture
- Some reclaimed areas may be used for pasture. Onsite investigation is needed to determine forage species to plant and various conservation practices to employ.

Woodland
- Some areas may be reclaimed for commercial woodland use. Onsite investigation is needed to determine tree species to plant and various conservation practices to employ.

Development
- Some areas may be reclaimed for development. Onsite investigation is needed to determine various engineering and conservation practices to employ.

VeB—Vergennes silty clay loam, 3 to 8 percent slopes

Setting

This soil is clayey, very deep, gently sloping, and moderately well drained. It is on summits and shoulders of lake plains in the Champlain Valley (fig. 24). Areas range from 3 to 375 acres in size.

Map Unit Composition

Major Components
Vergennes: 85 percent

Inclusions
Kingsbury: 5 percent
Cayuga: 4 percent
Claverack: 2 percent
Dunkirk: 2 percent
Unnamed: 2 percent

The somewhat poorly drained Kingsbury, Cayuga, Claverack, and well drained Dunkirk soils may be included in areas of this map unit. Also included are areas of moderately well drained soils that have a slightly lower clay content. Kingsbury soils occupy lower positions. Cayuga and Claverack soils occupy similar positions, but Cayuga soils are clayey over loamy, and Claverack soils are sandy over clayey. Dunkirk soils occupy slightly higher positions, and are silty and clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: farmland of statewide importance
Land capability classification: 2e

Hydric soil rating:
Vergennes: no
Hydrologic group:
Vergennes: D

Soil Properties and Qualities

Vergennes

Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: very high
Surface runoff potential: medium
Landform: lake plains
Parent material: clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
0 to 8 inches: very strongly acid to neutral (4.5 to 7.3)
8 to 10 inches: very strongly acid to neutral (4.5 to 7.3)
10 to 22 inches: very strongly acid to neutral (4.5 to 7.3)
22 to 29 inches: moderately acid to slightly alkaline (5.6 to 7.8)
29 to 37 inches: moderately alkaline (7.9 to 8.4)

Figure 24.—This photo is a good example of a dissected and gently sloping lake plain with Vergennes silty clay loam soils in the town of Ticonderoga. These soils have high native fertility but are very clayey, with greater than 60 percent clay in the subsoil, and often 40 to 50 percent clay in the surface. Tillage at the proper moisture content (neither too wet, nor too dry) is essential to maintain good soil structure. Compaction can be a severe problem on these soils. Many of these terraces may be marine (Champlain Sea era) in origin. Pasture and hayland production on these soils are good.

37 to 45 inches: moderately alkaline (7.9 to 8.4)
45 to 72 inches: moderately alkaline (7.9 to 8.4)

Permeability:

0 to 8 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
8 to 10 inches: very slow or slow (0.001 to 0.2 inches/hour)
10 to 22 inches: very slow or slow (0.001 to 0.2 inches/hour)
22 to 29 inches: very slow or slow (0.001 to 0.2 inches/hour)
29 to 37 inches: impermeable or very slow (0 to 0.06 inches/hour)
37 to 45 inches: impermeable or very slow (0 to 0.06 inches/hour)
45 to 72 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

Cropland

- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture

- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.

Woodland

- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Limiting log landing and haul road construction and operation activities to dry or frozen ground conditions will help overcome limitations caused by clayey soils.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Limiting timber harvesting operations to dry or frozen ground conditions will help overcome harvest equipment operability limitations caused by clayey soils.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard due to seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development

- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields

- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

VeC—Vergennes silty clay loam, 8 to 15 percent slopes

Setting

This soil is clayey, very deep, strongly sloping, and moderately well drained. It is on shoulders and backslopes of lake plains in the Champlain Valley. Areas range from 3 to 195 acres in size.

Map Unit Composition

Major Components
Vergennes: 85 percent

Inclusions
Cayuga: 4 percent
Dunkirk: 4 percent

Kingsbury: 4 percent
Unnamed: 3 percent

The Cayuga, well drained Dunkirk, and somewhat poorly drained Kingsbury soils may be included in areas of this map unit. Also included are areas of moderately well drained soils that have a slightly lower clay content. Cayuga soils occupy similar positions, but are clayey over loamy. Dunkirk soils occupy slightly higher positions, and are silty and clayey. Kingsbury soils occupy lower positions. Included areas can occupy about 15 percent of this unit.

  45 to 72 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.

- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Avoiding construction of log landings during periods of seasonal saturation, adequate design of drainage features such as diversion ditches, and applying coarse grained base material will help overcome suitability limitations caused by seasonal wetness. Riparian setbacks should be at least 200 feet.
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Limiting log landing and haul road construction and operation activities to dry or frozen ground conditions will help overcome limitations due to clayey soils.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Limiting timber harvesting operations to dry or frozen ground conditions will help overcome harvest equipment operability limitations caused by clayey soils.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when

excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

VeD—Vergennes silty clay loam, 15 to 25 percent slopes

Setting

This soil is clayey, very deep, moderately steep, and moderately well drained. It is on backslopes of lake plains in the Champlain Valley. Areas range from 3 to 305 acres in size.

Map Unit Composition

Major Components
Vergennes: 85 percent

Inclusions
Dunkirk: 5 percent
Unnamed: 5 percent
Cayuga: 4 percent
Kingsbury: 1 percent

The well drained Dunkirk, Cayuga, and somewhat poorly drained Kingsbury soils may be included in areas of this map unit. Also included are areas of well drained clayey soils. Dunkirk soils occupy slightly higher positions, and are silty and clayey. Cayuga soils occupy similar positions, but are clayey over loamy. Kingsbury soils occupy lower positions. Included areas can occupy about 15 percent of this unit.

Permeability:
  0 to 8 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
  8 to 10 inches: very slow or slow (0.001 to 0.2 inches/hour)
  10 to 22 inches: very slow or slow (0.001 to 0.2 inches/hour)
  22 to 29 inches: very slow or slow (0.001 to 0.2 inches/hour)
  29 to 37 inches: impermeable or very slow (0 to 0.06 inches/hour)
  37 to 45 inches: impermeable or very slow (0 to 0.06 inches/hour)
  45 to 72 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Subsurface drainage in low areas may extend the period of planting and harvesting of crops.
- Clods may form if the soil is tilled when wet.
- Controlling traffic during wet periods can minimize soil compaction.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Restricting grazing during wet periods can minimize compaction.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Limiting construction activities to dry or frozen ground conditions will help overcome construction limitations of haul roads caused by clayey soils.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Limiting timber harvesting operations to dry or frozen ground conditions will help overcome harvest equipment operability limitations caused by clayey soils.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

VeE—Vergennes silty clay loam, 25 to 45 percent slopes

Setting

This soil is clayey, very deep, very steep, and moderately well drained. It is on backslopes of lake plains in the Champlain Valley. Areas range from 3 to 445 acres in size.

Map Unit Composition

Major Components
Vergennes: 85 percent

Inclusions
Unnamed: 7 percent
Dunkirk: 6 percent
Cayuga: 2 percent

The well drained Dunkirk, and Cayuga soils may be included in areas of this map unit. Also included are areas of well drained clayey soils. Dunkirk soils occupy slightly higher positions, and are silty and clayey. Cayuga soils occupy similar positions, but are clayey over loamy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 6e

Hydric soil rating:
  Vergennes: no
Hydrologic group:
  Vergennes: D

Soil Properties and Qualities

Vergennes
Drainage class: moderately well drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 18 to 30 inches
  Water table kind: apparent
Flooding: none
Available water capacity: moderate
Potential frost action: moderate
Shrink-swell potential: very high
Surface runoff potential: high
Landform: lake plains
Parent material: clayey glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 8 inches: very strongly acid to neutral (4.5 to 7.3)
  8 to 10 inches: very strongly acid to neutral (4.5 to 7.3)
  10 to 22 inches: very strongly acid to neutral (4.5 to 7.3)
  22 to 29 inches: moderately acid to slightly alkaline (5.6 to 7.8)
  29 to 37 inches: moderately alkaline (7.9 to 8.4)
  37 to 45 inches: moderately alkaline (7.9 to 8.4)
  45 to 72 inches: moderately alkaline (7.9 to 8.4)
Permeability:
  0 to 8 inches: very slow to moderately slow (0.001 to 0.6 inches/hour)
  8 to 10 inches: very slow or slow (0.001 to 0.2 inches/hour)
  10 to 22 inches: very slow or slow (0.001 to 0.2 inches/hour)
  22 to 29 inches: very slow or slow (0.001 to 0.2 inches/hour)
  29 to 37 inches: impermeable or very slow (0 to 0.06 inches/hour)
  37 to 45 inches: impermeable or very slow (0 to 0.06 inches/hour)
  45 to 72 inches: impermeable or very slow (0 to 0.06 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- These soils are generally not recommended for pasture.

Woodland
- Avoiding construction during periods of seasonal saturation, adequate design of drainage features such as water bars and ditches, and maintaining grades of 3 to 10 percent will help overcome construction limitations of haul roads caused by seasonal wetness.
- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads caused by steep slopes.
- Limiting construction activities to dry or frozen ground conditions will help overcome construction limitations of haul roads caused by clayey soils.

- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations caused by steep slopes.
- Avoiding timber harvesting during periods of seasonal saturation or logging during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.
- Limiting timber harvesting operations to dry or frozen ground conditions will help overcome harvest equipment operability limitations caused by clayey soils.
- Restricting harvesting operations during months of seasonal saturation, logging when the ground is frozen, careful layout of skid trails to minimize the number of passes, using tracked instead of rubber tired skidders, and maintaining slash cover will help reduce the rutting hazard.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 150 feet.
- Selective harvesting systems that maintain enough canopy to prevent additional wind damage to residual trees will help overcome windthrow hazard caused by seasonal wetness. Plans for periodic salvaging of windthrow trees and maintenance of permanent road and trail systems is advisable.
- Consult the Water Features table for months of seasonal saturation.

Development
- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.
- Excessive shrink-swell in these soils results in a severely limited capacity to support a load without movement and can cause shifting foundations and cracking of basement walls and floors.
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The seasonal high water table in some areas of these soils may limit the absorption and proper treatment of the effluent from septic systems.
- The restricted movement of fluids through these soils limits the absorption and proper treatment of the effluent from septic systems. Referencing local and state regulations and installation of alternative systems may be necessary for properly developing this site.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Installing a drainage system and adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils may not be suitable for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

W—Water

This map unit consists of areas of permanent surface water. It includes lakes, ponds, and perennial rivers and streams that were cartographically large enough to delineate at the scale of mapping.

WeA—Wegatchie silt loam, 0 to 3 percent slopes

Setting

This soil is silty and clayey, very deep, nearly level, and poorly drained. It is on toeslopes of glacial-valley walls in the Adirondack Upland. Areas range from 3 to 100 acres in size.

Map Unit Composition

Major Components
Wegatchie: 85 percent

Inclusions
Hailesboro: 5 percent
Roundabout: 4 percent
Searsport: 3 percent
Burnt Vly: 2 percent
Unnamed: 1 percent

The somewhat poorly drained Hailesboro and Roundabout, and very poorly drained Searsport and Burnt Vly soils may be included in areas of this map unit. Also included are areas of poorly drained sandy over clayey soils. Hailesboro and Roundabout soils occupy higher positions, and Roundabout soils are silty. Searsport and Burnt Vly soils occupy slightly lower positions, Searsport soils are sandy, and Burnt Vly soils are mucky over sandy. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 4w
Hydric soil rating:
  Wegatchie: yes
Hydrologic group:
  Wegatchie: C/D

Soil Properties and Qualities

Wegatchie
Drainage class: poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: 0 to 12 inches
  Water table kind: apparent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: moderate
Surface runoff potential: very high
Landform: glacial-valley walls
Parent material: silty glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
  0 to 8 inches: moderately acid to neutral (5.6 to 7.3)
  8 to 13 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  13 to 19 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  19 to 40 inches: slightly acid to slightly alkaline (6.1 to 7.8)
  40 to 72 inches: neutral to moderately alkaline (6.6 to 8.4)

  8 to 13 inches: slow to moderate (0.06 to 2 inches/hour)
  13 to 19 inches: slow to moderate (0.06 to 2 inches/hour)
  19 to 40 inches: slow to moderate (0.06 to 2 inches/hour)
  40 to 72 inches: slow to moderate (0.06 to 2 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are poorly suited to cultivated crops due to the seasonal high water table.
- The root system of some deep-rooted crops may be damaged by frost action.
- Controlling traffic during wet periods can minimize soil compaction.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or early-maturing crop varieties is recommended.

Pasture
- Avoiding overgrazing can reduce the hazard of erosion.
- Excess water should be removed, or grass or legume species that are adapted to wet soil conditions should be planted.
- Restricting grazing during wet periods can minimize compaction.
- Planting adapted species can minimize the root damage caused by frost action.
- The growing season may be shorter for these soils than for soils at lower elevations. The use of short-season or frost-tolerant plant species is recommended.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations caused by wetness.

- Restricting harvesting operations during months of seasonal saturation or logging when the ground is frozen, carefully locating major skid trails and winching logs to them to reduce the skidder footprint, and using tracked skidders will help reduce the rutting hazard.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations caused by wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- The seasonal high water table severely limits the capacity of these soils to bear a load without movement. Special design of structures is needed to prevent damage caused by wetness. The seasonal high water table may restrict the period when excavations can be made and require a higher degree of construction development and building maintenance.

Septic Tank Absorption Fields
- The seasonal high water table in areas of these soils greatly limits the absorption and proper treatment of the effluent from septic systems. Costly measures may be needed to lower the water table around the absorption field, or to raise the absorption field.
- The moderate to slow rate of fluid movement through these soils may impede the absorption and proper treatment of the effluent from septic systems.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.

WlA—Whallonsburg mucky peat, 0 to 2 percent slopes

Setting

This soil is mucky, very deep, nearly level, and very poorly drained. It is on swamps in the Champlain Valley. Areas range from 4 to 100 acres in size.

Map Unit Composition

Major Components
Whallonsburg: 85 percent

Inclusions
Catden: 5 percent
Livingston: 4 percent
Covington: 3 percent
Rippowam: 2 percent
Gougeville: 1 percent

The Catden, Livingston, and poorly drained Covington, Rippowam and Gougeville soils may be included in areas of this map unit. Also included are organic soils with higher woody fragment content. Catden and Livingston soils occupy similar positions, but Catden soils are greater than 51 inches deep to mineral soil material, and Livingston soils are clayey. Covington and Gougeville soils occupy slightly higher positions, Covington soils are clayey, and Gougeville soils are sandy. Rippowam soils are loamy and are on small flood plain areas near streams. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 5w
Hydric soil rating:
  Whallonsburg: yes
Hydrologic group:
  Whallonsburg: C/D

Soil Properties and Qualities

Whallonsburg
Drainage class: very poorly drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: 16 to 51 inches to an abrupt textural change
Depth to seasonal high water table: 0 inches
  Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: very high
Surface runoff potential: negligible
Landform: swamps
Parent material: organic material over clayey glaciolacustrine deposits
Reaction (pH):
  0 to 2 inches: very strongly acid to neutral (4.5 to 7.3)
  2 to 12 inches: very strongly acid to neutral (4.5 to 7.3)
  12 to 20 inches: very strongly acid to neutral (4.5 to 7.3)
  20 to 23 inches: very strongly acid to neutral (4.5 to 7.3)
  23 to 30 inches: strongly acid to moderately alkaline (5.1 to 8.4)
  30 to 72 inches: strongly acid to moderately alkaline (5.1 to 8.4)
Permeability:
  0 to 2 inches: moderately slow to rapid (0.2 to 20 inches/hour)
  2 to 12 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  12 to 20 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  20 to 23 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
  23 to 30 inches: impermeable to slow (0 to 0.2 inches/hour)
  30 to 72 inches: impermeable to slow (0 to 0.2 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads caused by wetness.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard due to wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.
- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.

- Because excessive shrinking and swelling can cause roadways to buckle and pavement to crack, these soils are limited for use as a base material. Adding coarse-textured subgrade material can help overcome this limitation.
- The low bearing strength of these soils is generally unfavorable for supporting heavy loads. Special design of local roads and streets is needed to prevent the structural damage caused by low soil strength.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.

WnA—Windsor loamy sand, 0 to 3 percent slopes

Setting

This soil is sandy, very deep, nearly level, and excessively drained. It is on summits of proglacial deltas in the Champlain Valley. Areas range from 3 to 740 acres in size.

Map Unit Composition

Major Components
Windsor: 85 percent

Inclusions
Unnamed: 5 percent
Deerfield: 4 percent
Factoryville: 3 percent
Howard: 2 percent
Claverack: 1 percent

The moderately well drained Deerfield and Claverack, and well drained Factoryville and Howard soils may be included in areas of this map unit. Also included are areas of excessively drained sandy soils with a high gravel content. Deerfield and Claverack soils occupy slightly lower positions, and Claverack soils are sandy over clayey. Factoryville and Howard soils occupy similar positions, but Factoryville soils have finer sand textures, and Howard soils are loamy and gravelly. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 3s
Hydric soil rating:
  Windsor: no
Hydrologic group:
  Windsor: A

Soil Properties and Qualities

Windsor
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock

Reaction (pH):
0 to 10 inches: very strongly acid to slightly acid (4.5 to 6.5)
10 to 14 inches: very strongly acid to slightly acid (4.5 to 6.5)
14 to 19 inches: very strongly acid to slightly acid (4.5 to 6.5)
19 to 24 inches: very strongly acid to slightly acid (4.5 to 6.5)
24 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
0 to 10 inches: rapid or very rapid (6 to 60 inches/hour)
10 to 14 inches: rapid or very rapid (6 to 60 inches/hour)
14 to 19 inches: rapid or very rapid (6 to 60 inches/hour)
19 to 24 inches: rapid or very rapid (6 to 60 inches/hour)
24 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations caused by low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be problems in some places where this map unit is cleared for development.
- Erecting erosion and sediment control structures where appropriate and stabilizing the soil surface with mulch and vegetation following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

WnB—Windsor loamy sand, 3 to 8 percent slopes

Setting

This soil is sandy, very deep, gently sloping, and excessively drained. It is on summits and shoulders of proglacial deltas in the Champlain Valley. Areas range from 3 to 460 acres in size.

Map Unit Composition

Major Components
Windsor: 85 percent

Inclusions
Unnamed: 5 percent
Deerfield: 4 percent
Factoryville: 3 percent
Howard: 2 percent
Claverack: 1 percent

The moderately well drained Deerfield and Claverack, and well drained Factoryville and Howard soils may be included in areas of this map unit. Also included are areas of excessively drained sandy soils with a high gravel content. Deerfield and Claverack soils occupy slightly lower positions, and Claverack soils are sandy over clayey. Factoryville and Howard soils occupy similar positions, but Factoryville soils have finer sand textures, and Howard soils are loamy and gravelly. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

  19 to 24 inches: rapid or very rapid (6 to 60 inches/hour)
  24 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland
- Grassed waterways can be used in some areas to slow and direct the movement of water and reduce erosion.
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- These soils are well suited to pasture.
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table ‘Trees to Manage’ section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- These soils have no restrictions for development of dwellings with basements.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- These soils have no restrictions for development of local roads and streets.

WnC—Windsor loamy sand, 8 to 15 percent slopes

Setting

This soil is sandy, very deep, strongly sloping, and excessively drained. It is on shoulders and backslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 55 acres in size.

Map Unit Composition

Major Components
Windsor: 85 percent

Inclusions
Unnamed: 5 percent
Deerfield: 4 percent

Factoryville: 3 percent
Howard: 2 percent
Claverack: 1 percent

The moderately well drained Deerfield and Claverack, and well drained Factoryville and Howard soils may be included in areas of this map unit. Also included are areas of excessively drained sandy soils with a high gravel content. Deerfield and Claverack soils occupy slightly lower positions, and Claverack soils are sandy over clayey. Factoryville and Howard soils occupy similar positions, but Factoryville soils have finer sand textures, and Howard soils are loamy and gravelly. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland
Land capability classification: 4s
Hydric soil rating:
Windsor: no
Hydrologic group:
Windsor: A

Soil Properties and Qualities

Windsor
Drainage class: excessively drained
Depth to bedrock: greater than 60 inches
Depth to root-restrictive feature: none within 60 inches
Depth to seasonal high water table: greater than 60 inches
Flooding: none
Available water capacity: very low
Potential frost action: low
Shrink-swell potential: low
Surface runoff potential: very low
Landform: proglacial deltas
Parent material: sandy glaciolacustrine deposits derived from igneous and sedimentary rock
Reaction (pH):
0 to 10 inches: very strongly acid to slightly acid (4.5 to 6.5)
10 to 14 inches: very strongly acid to slightly acid (4.5 to 6.5)
14 to 19 inches: very strongly acid to slightly acid (4.5 to 6.5)
19 to 24 inches: very strongly acid to slightly acid (4.5 to 6.5)
24 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
0 to 10 inches: rapid or very rapid (6 to 60 inches/hour)
10 to 14 inches: rapid or very rapid (6 to 60 inches/hour)
14 to 19 inches: rapid or very rapid (6 to 60 inches/hour)
19 to 24 inches: rapid or very rapid (6 to 60 inches/hour)
24 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland
- Using a system of conservation tillage and planting cover crops may reduce the runoff rate and help to minimize soil loss by erosion.
- Plants may suffer from moisture stress during drier summer months because of the limited available water capacity. Incorporating crop residue or other organic matter into the surface layer increases the capacity of the soil to retain moisture.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland
- Seeding cut and fill areas after grading and leveling, applying gravel base material, and maintaining 200 foot riparian buffers will help overcome limitations of log landing suitability caused by strongly sloping areas.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development
- Erosion and sediment control can be problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements
- The slope influences the use of machinery and the ease of excavation. Special building practices and designs may be required to ensure satisfactory performance.

Septic Tank Absorption Fields
- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of strongly sloping areas, special design and installation techniques may be needed for the effluent distribution lines.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets
- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Placing roads on the contour can help overcome this limitation.

WnD—Windsor loamy sand, 15 to 25 percent slopes

Setting

This soil is sandy, very deep, moderately steep, and excessively drained. It is on backslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 80 acres in size.

Map Unit Composition

Major Components
Windsor: 85 percent

Inclusions
Unnamed: 5 percent
Howard: 4 percent
Factoryville: 3 percent
Deerfield: 2 percent
Claverack: 1 percent

The well drained Factoryville and Howard, and moderately well drained Deerfield and Claverack soils may be included in areas of this map unit. Also included are areas of excessively drained sandy soils with a high gravel content. Factoryville and Howard soils occupy similar positions, but Factoryville soils have finer sand textures, and Howard soils are loamy and gravelly. Deerfield and Claverack soils occupy slightly lower positions, and Claverack soils are sandy over clayey. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Farmland class: not prime farmland

Reaction (pH):
  0 to 10 inches: very strongly acid to slightly acid (4.5 to 6.5)
  10 to 14 inches: very strongly acid to slightly acid (4.5 to 6.5)
  14 to 19 inches: very strongly acid to slightly acid (4.5 to 6.5)
  19 to 24 inches: very strongly acid to slightly acid (4.5 to 6.5)
  24 to 72 inches: very strongly acid to neutral (4.5 to 7.3)
Permeability:
  0 to 10 inches: rapid or very rapid (6 to 60 inches/hour)
  10 to 14 inches: rapid or very rapid (6 to 60 inches/hour)
  14 to 19 inches: rapid or very rapid (6 to 60 inches/hour)
  19 to 24 inches: rapid or very rapid (6 to 60 inches/hour)
  24 to 72 inches: rapid or very rapid (6 to 60 inches/hour)

Use and Management

Cropland
- These soils are generally unsuited to use as cropland because of the slope and the erosion hazard.

Pasture
- Erosion control is needed when pastures are renovated.
- Avoiding overgrazing can reduce the hazard of erosion.
- Plants may suffer moisture stress during the drier summer months because of the limited available water capacity.

Woodland

- Maintaining road grades of 10 percent or less, installing properly spaced drainage structures, out sloping of roads, and reseeding bare surfaces will help overcome construction and maintenance limitations of haul roads due to steep slopes.
- Applying gravel base material during construction of haul roads will help overcome limitations caused by sandy surface layers.
- Constructing log landings on less sloping soils is recommended.
- Traversing slopes with trails that maintain grades of 10 percent or less and winching logs to these main skid trails will help overcome harvest equipment operability limitations due to steep slopes.
- Practices that will help minimize erosion include: carefully locating major skid trails prior to logging operations, with grades not exceeding 10 percent; avoiding skidding up and down slopes perpendicular to the contour; constructing and maintaining properly spaced water breaks on major skid trails and reseeding after logging operations. Riparian setbacks should be at least 100 feet.
- Traversing slopes on skid trails with grades not exceeding 10 percent and avoiding skidding operations during periods of seasonal saturation or unusually wet conditions will help reduce the rutting hazard.
- Managing for more drought tolerant timber species will help overcome seedling mortality limitations due to low water holding capacity in these soils. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

WnE—Windsor loamy sand, 25 to 45 percent slopes

Setting

This soil is sandy, very deep, very steep, and excessively drained. It is on backslopes of proglacial deltas in the Champlain Valley. Areas range from 3 to 215 acres in size.

Map Unit Composition

Major Components
Windsor: 85 percent

Inclusions
Unnamed: 5 percent
Factoryville: 4 percent
Howard: 4 percent
Claverack: 1 percent
Deerfield: 1 percent

The well drained Factoryville and Howard, and moderately well drained Deerfield and Claverack soils may be included in areas of this map unit. Also included are areas of excessively drained sandy soils with a high gravel content. Factoryville and Howard soils occupy similar positions, but Factoryville soils have finer sand textures, and Howard soils are loamy and gravelly. Deerfield and Claverack soils occupy slightly lower positions, and Claverack soils are sandy over clayey. Included areas can occupy about 15 percent of this unit.

Development

- Erosion and sediment control can be severe problems where this map unit is cleared for development.
- Minimizing soil disturbance, erecting erosion and sediment control structures, and stabilizing the soil surface with mulch and vegetation immediately following construction are practices that will help reduce these problems.

Dwellings with Basements

- The slope influences the use of machinery and the ease of excavation. Special building practices and designs are required to ensure satisfactory performance.

Septic Tank Absorption Fields

- The excessive rate of fluid movement through these soils limits the proper treatment of effluent from septic systems in areas of this map unit. The poorly treated effluent may pollute ground water in the area near the absorption field.
- Because of the slope, special design and installation techniques are needed for the effluent distribution lines. Onsite investigation may reveal lesser sloping inclusions that could be utilized.
- Onsite investigation is needed to determine the suitability of these soils for particular systems and to evaluate possible health and environmental risks.

Local Roads and Streets

- The slope of these soils impedes trafficability of heavy machinery and increases the difficulty and cost of building roads and streets. Special designs may be necessary.

WoA—Wonsqueak muck, 0 to 2 percent slopes

Setting

This soil is mucky, very deep, nearly level, and very poorly drained. It is on bogs and swamps in the Adirondack Upland. Areas range from 4 to 350 acres in size.

Map Unit Composition

Major Components
Wonsqueak: 85 percent

Inclusions
Bucksport: 5 percent
Typic Endoaquolls: 4 percent
Wegatchie: 3 percent
Rumney: 2 percent
Unnamed: 1 percent

The Bucksport, Typic Endoaquolls, and poorly drained Wegatchie and Rumney soils may be included in areas of this map unit. Also included are organic soils with higher woody fragment content. Bucksport and Typic Endoaquolls soils occupy similar positions, but Bucksport soils are greater than 51 inches deep to mineral soil material, and Typic Endoaquolls soils are loamy. Wegatchie soils occupy slightly higher positions and are silty and clayey. Rumney soils are loamy and are on small flood plain areas near streams. Included areas can occupy about 15 percent of this unit.

Interpretive Groups

Depth to seasonal high water table: 0 inches
Water table kind: apparent
Ponding: frequent
Flooding: none
Available water capacity: high
Potential frost action: high
Shrink-swell potential: low
Surface runoff potential: negligible
Landform: bogs, swamps
Parent material: organic material over loamy till
Reaction (pH):
    0 to 12 inches: extremely acid to slightly acid (4.0 to 6.5)
    12 to 25 inches: extremely acid to slightly acid (4.0 to 6.5)
    25 to 29 inches: neutral or slightly alkaline (6.6 to 7.8)
    29 to 72 inches: neutral or slightly alkaline (6.6 to 7.8)
Permeability:
    0 to 12 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

12 to 25 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
25 to 29 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)
29 to 72 inches: moderately slow to moderately rapid (0.2 to 6 inches/hour)

Use and Management

This map unit may contain important wetland habitat. Federal, State, and local regulations should be considered before draining or altering this area.

Cropland
- These soils are generally unsuited to cultivated crops due to ponding.

Pasture
- These soils are poorly suited to pasture due to ponding.

Woodland
- Locating roads on better drained soils or limiting road construction to drier parts of the year will help overcome construction limitations of haul roads due to wetness.
- Areas of poorly drained or very poorly drained soils should be avoided when locating log landings.
- Avoiding timber harvesting during months of seasonal saturation or harvesting during winter months when soils are frozen will help overcome harvest equipment operability limitations due to wetness.
- Areas of soils with thick organic surfaces should only be harvested in the winter months by tracked equipment in years when the soils are frozen and snow pack is deep enough to protect them from rutting.
- Selective harvesting systems that minimize canopy openings and reduce root system damage and maintenance of buffers around the upland edges may help overcome windthrow hazard caused by wetness.
- Managing for more wetness tolerant species will help overcome seedling mortality limitations due to wetness. Consult the Forestland Productivity table 'Trees to Manage' section for recommended species.
- Consult the Water Features table for months of seasonal saturation.
- Special forest management regulations may apply to wetland areas. In addition, special state and regional regulations may apply to construction or timber harvesting of any kind in wetland areas.

Dwellings with Basements
- Because of the potential for ponding, these soils are very limited as a site for dwellings with basements. The period when excavations can be made may be restricted and intensive construction site development and building maintenance may be needed.
- The potential for excessive subsidence in these soils severely limits the capacity to support a load without movement and can cause shifting or collapsing foundations and cracking of basement walls and floors.

Septic Tank Absorption Fields
- Because of ponding, these soils are very limited as a site for septic tank absorption fields.

Local Roads and Streets
- These soils are very limited for local roads and streets due to the potential for ponding. Seasonal ponding affects the ease of excavation and grading and limits the bearing capacity of the soil.
- The seasonal high water table impedes excavation and grading and reduces the bearing capacity of these soils. Adding suitable subgrade material to raise the road bed may help reduce this limitation.

- Local roads and streets may be damaged by frost action, which is caused by the freezing and thawing of soil moisture. The addition of coarse-textured subgrade material and supplemental drainage can help reduce this limitation.
- Subsidence of the organic material reduces the load-bearing capacity of these soils.

Prime Farmland

Prime farmland is one of several kinds of important farmland defined by the U.S. Department of Agriculture. It is of major importance in meeting the Nation's short- and long-range needs for food and fiber. Because the supply of high-quality farmland is limited, the U.S. Department of Agriculture recognizes that responsible levels of government, as well as individuals, should encourage and facilitate the wise use of our Nation's prime farmland.

Prime farmland, as defined by the U.S. Department of Agriculture, is land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and is available for these uses. It could be cultivated land, pastureland, forestland, or other land, but it is not urban or built-up land or water areas. The soil qualities, growing season, and moisture supply are those needed for the soil to economically produce sustained high yields of crops when proper management, including water management, and acceptable farming methods are applied. In general, prime farmland has an adequate and dependable supply of moisture from precipitation or irrigation, a favorable temperature and growing season, acceptable acidity or alkalinity, an acceptable salt and sodium content, and few or no rocks. It is permeable to water and air. It is not excessively erodible or saturated with water for long periods, and it either is not frequently flooded during the growing season or is protected from flooding. Slope ranges mainly from 0 to 6 percent. More detailed information about the criteria for prime farmland is available at the local office of the Natural Resources Conservation Service.

The survey area contains about 27,487 acres of prime farmland. That acreage makes up about 2.4 percent of the land area, and is located mainly in the Champlain Valley. Most of the active agricultural land remaining in the county today is prime farmland or farmland of statewide importance.

The map units in the survey area that are considered prime farmland are listed in table 5. This list does not constitute a recommendation for a particular land use. On some soils included in the list, measures that overcome a hazard or limitation, such as flooding, wetness, and droughtiness, are needed. Onsite evaluation is needed to determine whether or not the hazard or limitation has been overcome by corrective measures. The extent of each listed map unit is shown in table 4.

Also listed in the table are map units that are considered additional "Farmland of Statewide Importance." This farmland is an important part of the agricultural resource base in the area, but it does not meet the requirements for prime farmland. It is seasonally wet, cannot be easily cultivated, is more erodible than prime farmland, or is usually less productive than prime farmland. The location is shown on the detailed soil maps. The soil qualities that affect use and management are described under the heading "Detailed Soil Map Units."

Use and Management of the Soils

This soil survey is an inventory and evaluation of the soils in the survey area. It can be used to adjust land uses to the limitations and potentials of natural resources and the environment. Also, it can help to prevent soil-related failures in land uses.

In preparing a soil survey, soil scientists, conservationists, engineers, and others collect extensive field data about the nature and behavioral characteristics of the soils. They collect data on erosion, droughtiness, flooding, and other factors that affect various soil uses and management. Field experience and collected data on soil properties and performance are used as a basis in predicting soil behavior.

Information in this section can be used to plan the use and management of soils for crops and pasture; as forestland; as sites for buildings, sanitary facilities, highways and other transportation systems, and parks and other recreational facilities; and for agricultural waste management. It can be used to identify the potentials and limitations of each soil for specific land uses and to help prevent construction failures caused by unfavorable soil properties.

Planners and others using soil survey information can evaluate the effect of specific land uses on productivity and on the environment in all or part of the survey area. The survey can help planners to maintain or create a land use pattern in harmony with the natural soil.

Contractors can use this survey to locate sources of sand and gravel, roadfill, and topsoil. They can use it to identify areas where bedrock, wetness, or very firm soil layers can cause difficulty in excavation.

Health officials, highway officials, engineers, and others may also find this survey useful. The survey can help them plan the safe disposal of wastes and locate sites for pavements, sidewalks, campgrounds, playgrounds, lawns, and trees and shrubs.

Interpretive Ratings

The interpretive tables in this survey rate the soils in the survey area for various uses. Many of the tables identify the limitations that affect specified uses and indicate the severity of those limitations. The ratings in these tables are both verbal and numerical.

Rating Class Terms

Rating classes are expressed in the tables in terms that indicate the extent to which the soils are limited by all of the soil features that affect a specified use or in terms that indicate the suitability of the soils for the use. Thus, the tables may show limitation classes or suitability classes. Terms for the limitation classes are *not limited, somewhat limited,* and *very limited*. The suitability ratings are expressed as *well suited, moderately suited, poorly suited,* and *unsuited* or as *good, fair,* and *poor*.

Numerical Ratings

Numerical ratings in the tables indicate the relative severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.00 to 1.00. They indicate

gradations between the point at which a soil feature has the greatest negative impact on the use and the point at which the soil feature is not a limitation. The limitations appear in order from the most limiting to the least limiting. Thus, if more than one limitation is identified, the most severe limitation is listed first and the least severe one is listed last.

Crops and Pasture

Anita Deming, Executive Director of Cornell Cooperative Extension of Essex County, New York, helped to prepare this section.

Essex County has a long agricultural history. We have farms that have been productive since the French built Fort St. Frederic in Crown Point in 1734. Our land is rural and will stay rural as we are entirely within the protected Adirondack Park. We incorporate the fertile Champlain Valley, and several river valleys with a backdrop of beauty unrivaled in the Northeast. Our farms are small, independent operations with a wide range of products. History and scenic beauty meet in the Adirondacks.

Our soils are extremely diverse with lake-laid clays, stream terraces, bottom land alluvial deposits, and high lime calcareous glacial till in the Champlain Valley; acid till and glacial outwash as you move upland toward the Adirondack Mountains, and alluvial plain soils in the river valleys.

The topography ranges from 100 feet above sea level in the Champlain Valley to the top of Mount Marcy at 5,344 feet above sea level. Our USDA hardiness zones are 4a and 4b ranging from -20 degrees F to -30 degrees F. In our primary agricultural areas the average date of last frost is May 20 and first frost is Sept 30, giving a 140 day freeze-free season and 210 growing degree days (base 50 degrees F). The average May to September rainfall is 16 inches.

Agricultural Industry

- Diverse wholesale agriculture includes: dairy, apples, maple, potatoes, and organic grains (fig. 25).
- We also support a wide variety of direct market farms, that sell to a strong tourist industry seeking high-quality unusual products sold through local restaurants and stores.

Agricultural Support Services

- Three agricultural research stations Field Crops, Potatoes, and Maple, offer state-of-the art consultation for producers.
- A regional fruit specialist offers specialized programming for apples, small fruit, and grapes.
- Champlain Valley Milling, an organic grain mill, is located in Westport.
- Strong agricultural support services surround us in Addison County, Vermont and Clinton and Washington counties in New York.
- Adirondack Harvest promotes our products throughout the region and beyond.
- We have 54,000 acres in New York State approved agricultural districts (fig. 26).

Strong Markets

- Our image is one of a pure, wholesome environment that produces quality products inside the Adirondack Park.
- The Adirondacks see over 10 million visitors a year, and residents support local food options.
- You can easily reach New York City, Boston, or Montreal with a five hour or less trip by Interstate.
- For more information on opportunities in Essex County check our websites. http://counties.cce.cornell.edu/essex/ and www.adirondackharvest.com

Figure 25.—Black Angus cattle in the town of Willsboro. The soils are Vergennes silty clay loam.

Figure 26.—Alfalfa production in the town of Essex. The soils are Vergennes silty clay loam.

Managing Cropland

General management needed for crops and pasture is suggested in this section. Planners of management systems for individual fields or farms should consider the detailed information given in the description of each soil under the heading "Detailed Soil Map Units." Specific information can be obtained from the local office of the Natural Resources Conservation Service, or Cornell Cooperative Extension of Essex County.

The total land in farms and number of farms within Essex County in 2002 was 55,022 acres on 236 farms, making up about 5 percent of the land area of the county (US Census of Agriculture, 2002). Approximately 50 percent of that total, or 27,433 acres was cropland or permanent pasture. The remaining 27,567 acres was woodland or other land. Dairy products led total sales in 2002 with $4,241,000 or about 49 percent of agricultural sales, ranking 47 of 62 counties in the state. Hay and other crops ranked next with $1,378,000 or 16 percent of sales. Other products, including maple syrup, seed potato, and beef production, were next with $949,000 in sales or 11 percent. This was followed by vegetables with $871,000 in sales or 10 percent and orchards with $628,000 in sales or 7 percent of the total sales. Finally, nursery and greenhouse was $565,000 or 7 percent of total agricultural sales (NYASS, 2002).

The acreage in crops and pasture has declined steadily in the last few decades due to nonfarm development and idling. There is a continuing trend towards fewer but larger farms. This is similar to national trends.

Some general principles of crop production in Essex County are described in the following paragraphs.

Erosion can be a hazard on about two thirds of the potential cropland in the county. Potential cropland for this discussion has slopes not exceeding 15 percent, does not have a very stony or bouldery surface, and is not poorly drained or very poorly drained (hydric). About 35 percent of the potential cropland in the county is not highly erodible, 50 percent is potentially highly erodible, and about 15 percent is rated as highly erodible. The rate of erosion is related to the slope length and steepness of the land, the soil type and texture, the amount and intensity of the rainfall, and the type and density of vegetative cover. Vergennes, Amenia, and Pittsfield soils on 3 to 8 percent slopes are rated as potentially highly erodible, while these same soils on 8 to 15 percent slopes are rated as highly erodible. Kingsbury soils on 0 to 3 percent slopes are not highly erodible. Windsor soils on 0 to 3, and 3 to 8 percent slopes are not highly erodible, while these same soils on 8 to 15 percent slopes are only potentially highly erodible. In general, silt loams are the most erodible, followed closely by silty clay loams and clays. Loams and sandy loams are intermediate in erodibility, and sandy soils have the lowest erosion hazard on comparable slopes.

Water erosion is characterized by three phases, sheet, rill, and gully, with the latter being the most drastic and damaging. Accelerated erosion results in the loss of plant nutrients and available soil moisture for plant growth, the formation of rills and gullies, deterioration of tilth and soil structure, sedimentation of downslope areas, and the pollution of water bodies. Accelerated soil erosion also affects wildlife and recreation resources and presents a cost of remediation and repair to local economies. Soil productivity decreases when the surface layer is lost and increasing amounts of subsoil are incorporated into the plow layer. This is especially true in areas of soils that have fine textured subsoil such as Vergennes soils, and soils with root restricting layers such as Amenia.

Erosion control is generally needed on soils that have slopes of greater than five percent. Soils that have a high content of silt and few or no rock fragments, such as Hartland and Dunkirk soils, are highly susceptible to water erosion. The erosion-control effectiveness of a single or group of conservation practices differs from one soil to another, and different combinations can be equally effective in some areas. Erosion

control practices provide protective cover, reduce the runoff rate, and increase the rate of water infiltration into the soil profile. The latter provides more water for plant growth. Many tillage and conservation practices help to control erosion, and a combination of practices is generally recommended especially as the degree and/or length of slope increases. The use of residue management practices, such as zone-till and mulch tillage, cover crops, and crop rotations that include grasses and legumes, are effective in protecting the soil surface and reducing erosion. Contour tillage, stripcropping, and the use of diversions break up the slope, reduce overland flow, and reduce the erosion hazard. Limiting the number of years of tillage in a corn-hay rotation will also help reduce the risk of erosion. A local representative of the Natural Resources Conservation Service or the Soil and Water Conservation District can assist in planning an effective combination of practices to reduce soil erosion.

Seasonal wetness may delay planting or cause crop damage in areas of somewhat poorly drained soils of the county. About 20 percent of the potential cropland in the county is made up of somewhat poorly drained areas of Kingsbury, Stafford, Cosad, Massena, and Malone soils. Drainage can be facilitated by surface or subsurface design systems, or a combination of both. Surface systems such as diversion ditches, divert upslope runoff away from low-lying areas. Subsurface systems entail burying drainage tile at regularly spaced intervals to remove internal soil water from wetter low-lying areas. Establishing drainage outlets is sometimes difficult and expensive because of the low position of these soils on the landscape. Soil texture affects internal drainage of soils. Kingsbury soils that have very high clay content and very slow internal drainage may require narrower spacing of tile lines in pattern drainage systems than loamy soils such as Massena with moderate internal drainage, and sandy soils such as Stafford with relatively rapid internal drainage (fig. 27). Benefits of drainage by removing excess water are: permits more efficient machine operations; limits planting delays from wetness; increases soil air supply for good root growth; increases the uptake of nutrients; permits use of heavy harvesting equipment; increases crop yields; and increases farm property values (Cornell University, 1987).

Figure 27.—Tile drainage in Massena soils in the town of Chesterfield. Loamy Massena soils respond well to tile drainage. Note the numerous stones in the excavated material.

Available water capacity is an important factor that affects crop growth. Some soils in the county tend to be droughty. Sandy and gravelly soils and soils that are shallow over bedrock tend to have a fairly low available water capacity. The sandy Windsor and Champlain, and the gravelly Colton soils have a very low available water capacity. Maintaining or increasing the content of organic matter and improving soil structure increase the available water capacity of these droughty soils. Cover crops that are incorporated during tillage operations, crop residue, and the addition of manure increase the organic matter content and improve soil structure and tilth.

Soil tilth is an important factor affecting the movement and storage of water, air, and nutrients. It affects the health of roots and other soil organisms. Good soil tilth reduces erosion and enhances ease of cultivation. Soils with good tilth generally have granular structure and are porous. The soils can be kept granular and porous by cultivating at the proper moisture content, by including sod and cover crops in the crop rotation, and by properly managing crop residue or adding manure to increase organic matter content.

Tillage operations can influence soil tilth. Excessive tillage tends to reduce the content of organic matter and break down soil structure. Excessively drained, coarse-textured soils such as Windsor, Adams, and Colton, can be tilled throughout a wide range in moisture content without significant deterioration of tilth. Tilling wetter and finer textured soils such as Vergennes, Kingsbury, Collamer, and Niagara at the proper moisture content, helps to prevent deterioration of soil structure and the formation of impervious subsurface plow pans. Tilling when such soils are wet, results in puddling and the formation of hard surface crusts. Also, clods usually develop as the soils dry. Cultivating the soils at the proper moisture content, incorporating cover and sod crops in the cropping system, returning crop residue to the soil, and adding manure to increase organic matter content, help to keep the soils granular and porous.

Compaction can be a serious problem on the marine or lake-laid clay soils found in the Champlain Valley. Vergennes, Kingsbury, Covington, and Livingston soils have very high clay content and make up the bulk of these soils. Compaction destroys soil structure greatly increasing bulk density. This in turn impedes root penetration and water and air movement through the soil. Water, air, and nutrient uptake by roots is delayed and crop yields are reduced or crops fail. Infiltration rates are reduced in compacted surfaces, and subsequent overland flow during storm events greatly increases the hazard of erosion. Compaction is generally caused by the load exerted on the soil surface by tractor wheels and by the tillage equipment itself, during tillage operations when the soils are too wet. As wetness increases, the bearing capacity of these heavy clay soils decreases. More intensively tilled soils have greater compaction problems. Some remedies that may be applied to address compaction problems are: use plow layer compaction—plow with moldboard or chisel plow, but reduce secondary tillage; apply primary tillage before winter if no erosion danger exists; use zone builders; increase organic matter editions; avoid subsoil compaction—don’t travel on soils that are wet; improve soil drainage; use deep tillage with a subsoiler; use cover crops or rotation crops that penetrate compacted soils; use better load distribution; use controlled traffic; avoid wheel traffic in open furrows (SARE, 2009).

Soil fertility is important for optimum crop production. The soils in the county require lime and/or fertilizer for optimum production, and some require both. There are areas of the county where soil pH is not a problem due to the native lime content of the soil. The amount of lime and fertilizer needed depends on the natural content of lime and plant nutrients, the needs of a particular crop, and on the level of desired yields. Regular soil sampling for fertility analysis is highly recommended. The test results will provide information for application at agronomic needs that results in economic savings and helps prevent water pollution due to over-application and polluted runoff.

The content of organic matter is an important factor affecting fertility. Organic matter has high nutrient holding and exchange capacity, and high moisture holding capacity. Organic matter contents very widely in the agricultural soils of the county and depend on many variables including soil texture, drainage, acidity, and cropping history. Intensively tilled soils generally have lower organic matter levels than permanent pasture. Well drained soils have lower organic matter content than wetter soils. Coarser textured soils such as sands have lower organic matter content than loams or clays. Acidic soils tend to have higher organic matter content than high lime soils. Building up organic matter levels of cropland is always a good practice.

Nitrogen is released from the organic matter, but much of it is in complex forms that cannot be used by growing plants until it is decomposed by soil microorganisms. Nitrogen fertilizer is needed to supplement the plant available nitrogen from the organic matter in the soil. Management practices that increase the content of organic matter, such as cover crops, sod in rotation, and crop residue management increase the content of nitrogen.

Timeliness of nitrogen fertilization is important to ensure its maximum use by plants. Nitrogen can be lost through leaching in rapidly permeable soils, such as Windsor soils, or by denitrification in wetter and less permeable soils such as Kingsbury. The best results can be obtained by applying small amounts of nitrogen at the proper intervals (e.g. split applications) and by using the pre-sidedress nitrogen test (PSNT)). In split applications, the nitrogen is applied at the time of planting and later as a side-dressing when the crop is growing.

While overall phosphorous content of agricultural soils in Essex County is moderate, the native content is variable. It tends to be very low in coarse-textured soils such as Windsor. Additions of the appropriate amounts of phosphate in the form of commercial fertilizer are essential in areas used by crops. Phosphorous content of feeds brought into the farm and manure applied to cropland should be taken into account in a farm nutrient budget that is based on regular soil and feed analysis.

Most of the soils in the county have low or medium levels of available potassium. The potassium-supplying power of a soil depends upon the clay content. Soils such as Vergennes and Kingsbury are somewhat higher in potassium since they have clayey subsoils. Even soils that have a fairly high content of potassium require additional potassium for the optimum yields of most crops.

Lime is needed on many of the soils in the county to raise the reaction (pH) to a level that will ensure the optimum yields of most crops. Many of the soils in the Champlain Valley overlie or were formed in deposits derived from limestone. Typically, they do not require as much lime as soils in the other parts of the county. Examples of high lime soils in the county are the Vergennes, Kingsbury, Nellis, Amenia, Pyrities, Kalurah, and Howard soils. Additions of lime and fertilizer should be based on the results of soil tests. For assistance in obtaining soil tests and recommendations, farmers and others can contact Cornell Cooperative Extension of Essex County in Westport.

In most areas of Essex County (about 82 percent of the land area), surface stones, boulders, and rock outcrops severely limit the use of the soils as cropland or pasture. They interfere with the use of farming equipment. Some small areas of very stony or very bouldery soils, such as “723C—Becket fine sandy loam, 3 to 15 percent slopes, very bouldery” could be used as permanent pasture. Applying fertilizer, reseeding, and mowing would be difficult in these areas. Removing the larger stones and boulders from some of these soils that have few additional limitations may be feasible. Overcoming limitations in areas of significant rock outcrop such as “831C—Tunbridge-Lyman complex, 3 to 15 percent slopes, very rocky, very bouldery”, is generally not feasible. Most of these areas with significant rock outcrop and/or very bouldery or very stony surfaces are better suited to woodland management.

Yields per Acre

The average yields per acre that can be expected of the principal crops under a high level of management are shown in table 6. In any given year, yields may be higher or lower than those indicated in the table because of variations in rainfall and other climatic factors. The land capability classification of map units in the survey area also is shown in the table.

Yields were generated by Cornell University's Forages.org website utilizing the Forage Species Selection Tool. The Forage Species Selection Tool is made up of several computer programs which access numerous databases to provide forage species suggestions for New York State, taking into consideration both the available soil type and the intended forage use. The website is at: http://forages.org/ (Cornell University, 2008).

The management needed to obtain the indicated yields of the various crops depends on the kind of soil and the crop. Management can include drainage, erosion control, and protection from flooding; the proper planting and seeding rates; suitable high-yielding crop varieties; appropriate and timely tillage; control of weeds, plant diseases, and harmful insects; favorable soil reaction and optimum levels of nitrogen, phosphorus, potassium, and trace elements for each crop; effective use of crop residue, barnyard manure, and green manure crops; and harvesting that ensures the smallest possible loss.

The estimated yields reflect the productive capacity of each soil for each of the principal crops. Yields are likely to increase as new production technology is developed. The productivity of a given soil compared with that of other soils, however, is not likely to change.

Crops other than those shown in table 6 are grown in the survey area, but estimated yields are not listed because the acreage of such crops is small. The local office of the Natural Resources Conservation Service or of the Cooperative Extension Service can provide information about the management and productivity of the soils for those crops.

Land Capability Classification

Land capability classification shows, in a general way, the suitability of soils for most kinds of field crops. Crops that require special management are excluded. The soils are grouped according to their limitations for field crops, the risk of damage if they are used for crops, and the way they respond to management. The criteria used in grouping the soils do not include major and generally expensive landforming that would change slope, depth, or other characteristics of the soils, nor do they include possible but unlikely major reclamation projects. Capability classification is not a substitute for interpretations designed to show suitability and limitations of groups of soils for rangeland, for forestland, or for engineering purposes.

In the capability system, soils are generally grouped at three levels—capability class, subclass, and unit.

Capability classes, the broadest groups, are designated by the numbers 1 through 8. The numbers indicate progressively greater limitations and narrower choices for practical use. The classes are defined as follows:

Class 1 soils have slight limitations that restrict their use.

Class 2 soils have moderate limitations that restrict the choice of plants or that require moderate conservation practices.

Class 3 soils have severe limitations that restrict the choice of plants or that require special conservation practices, or both.

Class 4 soils have very severe limitations that restrict the choice of plants or that require very careful management, or both.

Class 5 soils are subject to little or no erosion but have other limitations, impractical to remove, that restrict their use mainly to pasture, rangeland, forestland, or wildlife habitat.

Class 6 soils have severe limitations that make them generally unsuitable for cultivation and that restrict their use mainly to pasture, rangeland, forestland, or wildlife habitat.

Class 7 soils have very severe limitations that make them unsuitable for cultivation and that restrict their use mainly to grazing, forestland, or wildlife habitat.

Class 8 soils and miscellaneous areas have limitations that preclude commercial plant production and that restrict their use to recreational purposes, wildlife habitat, watershed, or esthetic purposes.

Capability subclasses are soil groups within one class. They are designated by adding a small letter, *e, w, s,* or *c,* to the class numeral, for example, 2e. The letter *e* shows that the main hazard is the risk of erosion unless close-growing plant cover is maintained; *w* shows that water in or on the soil interferes with plant growth or cultivation (in some soils the wetness can be partly corrected by artificial drainage); *s* shows that the soil is limited mainly because it is shallow, droughty, or stony; and *c,* used in only some parts of the United States, shows that the chief limitation is climate that is very cold or very dry.

In class 1, there are no subclasses because the soils of this class have few limitations. Class 5 contains only the subclasses indicated by *w, s,* or *c* because the soils in class 5 are subject to little or no erosion. They have other limitations that restrict their use to pasture, rangeland, forestland, wildlife habitat, or recreation.

Capability units are soil groups within a subclass. The soils in a capability unit are enough alike to be suited to the same crops and pasture plants, to require similar management, and to have similar productivity. Capability units are generally designated by adding an Arabic numeral to the subclass symbol, for example, 2e-4 and 3e-6. These units are not given in all soil surveys.

The capability classification of map units in this survey area is given in the section “Detailed Soil Map Units” and in table 6.

Forest Productivity and Management

The county is 90 percent forested according to the US Forest Service (Alerich and others, 1995). Privately owned timberlands comprise about 50 percent of the land area in Essex County, or approximately 576,000 acres. The rest of the forestland is part of the New York State Adirondack Park and is reserved from timber harvest under State law. About 17 percent of the land area of the county is owned and operated by large industrial forestry companies.

Essex County lies wholly within the Adirondack Park. Of the State-owned lands, about 310,000 acres is designated Wilderness Lands, which include the High Peaks, McKenzie Mountain, Sentinel Range, Jay Mountain, Giant Mountain, Dix Mountain, Hoffman Notch, and Pharoah Lake Wilderness Areas. Nearly 150,000 acres is designated Wild Forest Lands; these areas include the Vanderwhacker Mountain, Hammond Pond, and several smaller Wild Forest Areas. About 20,000 acres is designated Primitive; these areas include the Hurricane Mountain and Hudson Gorge Primitive Areas. Of all the State-owned lands in Essex County, about 15 percent is considered unproductive forestland. Unproductive forestland is incapable of producing 20 cubic feet per acre of industrial wood under natural conditions because of adverse site conditions.

Of the US Forest Service recognized forest-type groups in the county, Northern Hardwoods cover the greatest area of private forestland including about 255,000 acres (Alerich and others, 1995). The Eastern White Pine/Red Pine group covers about 127,000 acres. The Red Spruce/Balsam Fir group covers about 72,000 acres. The

Northern Red Oak/Shagbark Hickory group covers about 69,000 acres. The Northern Red Oak/Eastern White Pine group covers about 32,000 acres, and the Big Tooth Aspen/Paper Birch group covers about 20,000 acres.

The Northern Hardwood type consists mainly of American Beech, Sugar Maple, and Yellow Birch, although some sites include Black Cherry, White Ash, Eastern White Pine, and Red Maple. Northern hardwoods are most common on well drained and moderately well drained glacial till soils that dominate side slopes of mountains and hills in the Adirondack Upland. Examples of these tills are the Becket, Tunbridge, Monadnock, Skerry, and Sunapee soils. On wetter footslope areas of these till landscapes, Eastern Hemlock, Red Spuce, and Balsam Fir are mixed with the dominant Beech, Birch, and Maple. Adirondack and Tahawus soils mostly occupy these landforms.

The Easter White Pine/Red Pine type grows most commonly on excessively drained, droughty, sandy glacial outwash soils along river valleys in the Adirondack Upland and Champlain Valley, but can also be found on shallow to gneiss bedrock landforms generally below 2,000 feet in elevation, which are also subject to moisture stress. Associates of White and Red Pine on sandy outwash terraces are Northern Red Oak, Pitch Pine, Eastern White Cedar, Paper Birch, and Sugar Maple. Adams, Colton, Windsor, and Duxbury are examples of soils that occupy these landforms (fig. 28). Associates of White and Red Pine on shallow to bedrock hilltops and steep, moderately deep side slopes are Northern Red Oak, Black Cherry, White Ash, Sugar Maple, and American Beech. Lyman, Tunbridge, Knob Lock, Hollis, and Chatfield are examples of soils found on these landforms.

The Red Spruce/Balsam Fir type grows mainly on poorly drained depressions and bogs in the Adirondack Upland, and on mountaintops above an elevation of 3,000 feet, but can also be found in lowland, hummocky, well drained to very poorly drained, ablation till areas in the Adirondack Upland. In depressions and bogs, Eastern White Cedar, Black Spruce, Tamarack, Eastern Hemlock, and Eastern White Pine can be associates of the dominant Spruce and Fir. Tahawus, Adirondack, Burnt Vly, and Pleasant Lake are examples of soils that occupy these landforms. Harsh weather and thinner soils limit tree growth on mountaintops, and in these stands, Mountain Paper Birch is mixed with the Spruce and Fir. Esther, Wallface, Santanoni, Skylight, Couchsachraga, and Ricker soils occupy these landforms. In the lowland ablation till areas, Yellow Birch, Red Maple, and White Pine are common associates. Monadnock, Sunapee, and Tahawus soils occupy these landforms.

The Northern Red Oak/Shagbark Hickory type grows mainly on somewhat excessively drained, well drained, and moderately well drained, high lime, high fertility soils of till, lacustrine, and outwash origin found in the Champlain Valley. This forest type can be found on landforms in the valley that have not been cleared for agriculture including drumlin-like ridges made up of calcareous loamy tills, calcareous sandy and gravelly outwash deposits, shallow to limestone bedrock terraces and scarps, and clayey lacustrine terraces. Eastern White Pine, White Ash, American Basswood, Sugar Maple, White Oak, and American Elm are associated with Red Oak and Hickory in these areas. Nellis, Amenia, Colonie, Howard, Farmington, Galway, and Vergennes are examples of soils that occupy these landforms.

The Northern Red Oak/Eastern White Pine group grows mainly on well drained and somewhat excessively drained soils of low to medium fertility, and of till or glacial outwash origin. This forest type can be found on acid and medium lime tills associated with bedrock controlled hills, and on acid and medium lime sandy deltaic outwash deposits in the Champlain Valley. American Beech, Sugar Maple, Yellow Birch, White Ash, Red Maple, Paper Birch, and Red Pine are associated with Red Oak and White Pine in these areas. Charlton, Chatfield, Pittsfield, Georgia, Windsor, and Deerfield are examples of soils that occupy these landforms.

Figure 28.—Naturally seeded stand of White and Red Pine on a flat-lying glacial outwash terrace of Colton soils in the town of Lewis. White Pine and Red Pine stands are typically found on these excessively drained sandy and gravelly soils. Note this map unit of Colton has more stones than is typical, and internal drainage is probably very rapid.

The Big Tooth Aspen/Paper Birch type can be found all over the county usually on disturbed or reforested sites. This forest type can occupy a wide range of soil conditions. The sites are usually transitional to some climax forest type and are generally abandoned farmland, or areas that have undergone some disturbance such as forest fire or land clearing at some point in the past.

According to the US Forest Service, most private timberlands in Essex County (about 38 percent) are overstocked. About 27 percent of private timberlands are fully stocked and 28 percent are moderately stocked (Alerich and others, 1995). Only 7 percent of private timberlands are poorly stocked. In 1993, net volume of sawtimber trees on private timberland in Essex County was 3,093 million board feet. The volume increased about 27 percent between 1980 and 1993, mainly the result of maturing

forest stands. Northern hardwoods produced about 1,321 million board feet; oak-pine and oak-hickory about 500 million board feet; other hardwoods, 100 million board feet; spruce-fir, 266 million board feet; and pine, 907 million board feet.

According to the US Forest Service productivity class rating, 68 percent of private timberlands are rated in the poor productivity class, 22 percent in the fair productivity class, only 9 percent in the good productivity class, and 1 percent in the very good productivity class (Alerich and others, 1995). Conversely, according to the Essex County Forestland Soil-Site Feasibility Study (Craul, 1987), 47 percent of the county's private commercial timberland is rated in the very good productivity class, 21 percent in the good productivity class, 13 percent in the fair productivity class, and 19 percent in the poor productivity class. Productivity class of a site is based on its ability to produce a range of volume of timber in cubic feet per acre per year: very good— 120+ cu/ ft./acre/yr; good— 85 - 119 cu/ ft./acre/yr; fair—50 - 84 cu/ ft./acre/yr; poor— 20 - 49 cu/ ft./acre/yr. Estimates of productivity class for Essex County woodlands vary widely. Even more elusive is data that ties productivity class directly to soil type. From what little data exists, some trends seem to appear and are reflected in table 7 (Forestland Productivity). Highest productivity for timber species seems to occur on soils that are also the best agricultural soils in the county. High lime, nutrient rich, relatively warm soils found in the Champlain Valley of till, outwash, or lacustrine origin, seem to have the highest productivity classes for any given timber species. Warmer climates favor certain species such as oaks and hickory. As parent materials of any geologic origin (till, outwash, lacustrine, alluvial) become more acidic, productivity generally decreases. As one moves from east to west in the county, and climatic conditions become colder and growing season becomes shorter, productivity generally decreases. As one climbs in elevation in the mountainous areas of the county and the climate becomes colder, productivity decreases as does the appearance of many commercially important timber species such as Sugar Maple. Deep soils with higher available moisture throughout the growing season are more productive than soils that are shallow to bedrock or have root restricting layers like a dense substratum. Loamy soils that have higher available moisture are generally more productive than sandy or gravelly soils where plants seasonally suffer from moisture stress. Soils that are restricted in rooting depth by seasonal high water tables at or near the surface, are generally less productive. With the soil survey, foresters can assess the relative productivity of timberlands for sustained yield.

During timber harvesting operations, soil erosion, and degradation of soil quality and site productivity are potential risks, but with proper planning and execution, these risks can be minimized. A soil map, a topographic map, and a hand level or clinometer to measure steepness of slope, are a few tools a timber harvester, forester, or landowner can employ to plan their operation to help protect the soil resource. Locations of haul roads, log landings, stream crossings, and major skid trails should all be planned before operations begin. High risk areas of the tract, whether for erosion, soil rutting, stream sedimentation, or construction hazard can be indicated on the base maps and proper measures to minimize the hazards can be addressed.

Type of geologic deposit or parent material, depth to seasonal high water table, depth to bedrock, and slope are the primary soil characteristics that affect how a soil will behave during timber harvesting operations. About 80 percent of the soils in the county formed in material that was deposited by glacial ice, or "till". Most till has a fine sandy loam or sandy loam subsoil, and are reasonably stable material for building roads and landings and running skidding equipment, provided it is relatively dry. Most of this till was deposited at the base of flowing glaciers and has a dense substratum, or hard pan, about 30 inches below the surface. In the spring when the snow is melting, or in peak rainy periods, water will percolate through the friable subsoil and "perch" on top of this hardpan and form a shallow perched water table. On strongly sloping or steep areas, or gently sloping areas where the convex shape of the

landform sheds water off the slope, this water table exists only for brief periods. On footslopes, toeslopes, benches, and saddles that receive additional upslope runoff, seasonal high water tables perched on the hardpan can persist much longer into the growing season. When these soils are saturated from the perched water table, they become soft and unstable and unable to bear a load without deformation. Rubber tire skidders can create huge ruts that can lead to gullying, accelerated erosion, and stream sedimentation. Rutting will also alter local hydrology impeding drainage and increasing wetness, and it will destroy soil structure, reduce soil health, and degrade site quality. Becket, Mundalite, Skerry, Amenia, Adirondack, and Ampersand are examples of till soils with a dense substratum. Some tills were deposited when they were "dumped" out of stagnant ice as it was mass wasting at the end of glaciation as the climate warmed. These tills are generally friable throughout the profile, are free draining and lack the perched water tables, and are generally more stable except during brief periods in the spring and unusual wet periods. Monadnock, Hermon, and Fernlake are examples of these ablation tills. Excessively drained sandy and gravelly outwash soils, such as Colton and Adams, are very stable and present very little problems for timber harvesting operations except on steep slopes. Flood plain soils are mostly fine sandy loams or silt loams and if seasonally saturated are unstable and can be subject to rutting, erosion from flooding, and site degradation problems as discussed above. Ondawa, Podunk, Rumney, Lovewell, Cornish, and Charles are examples of these flood plain soils. Lacustrine or glacial lake deposited soils range from silt to clay in texture and are very unstable when seasonally saturated. Vergennes, Kingsbury, Depeyster, Dunkirk, and Nicholville are examples of lacustrine soils. Timber harvesting operations on any of the different soil parent materials mentioned above should be avoided during periods of seasonal saturation. Soils that are poorly drained and have water tables at or near the surface for most of the year should be harvested only during the winter when soils are frozen and snow cover protects the soil surface. Consult the Water Features table for depth and duration of seasonal high water tables. Steep slopes are also a problem when conducting timber harvesting operations because of the risk of erosion, stream sedimentation, and overall degradation of site quality. Proper planning and location of haul roads, and major and minor skid trails, will help reduce erosion on steep slopes. Haul roads and major skid trails should traverse the slope never exceeding grades of 10 percent even on stable sandy or gravelly soils. Operation of rubber tire skidders on steep slopes should be suspended during wet periods because of increased risk of soil rutting.

Proper closing of roads and trails after a timber harvest will help minimize erosion. Water bars should be installed on any road with slopes greater than 3 percent to divert water off the road. As slope increases, water bars should be placed more closely together. Seeding roads and landings will further stabilize the soil and has the added effect of enhancing habitat for wildlife.

The tables in this section can help forest owners or managers plan the use of soils for wood crops. They show the potential productivity of the soils for wood crops and rate the soils according to the limitations that affect various aspects of forest management.

Forest Productivity

In table 7, the *potential productivity* of merchantable or *common trees* on a soil is expressed as a site index and as a volume number. The *site index* is the average height, in feet, that dominant and codominant trees of a given species attain in a specified number of years. The site index applies to fully stocked, even-aged, unmanaged stands. Commonly grown trees are those that forest managers generally favor in intermediate or improvement cuttings. They are selected on the basis of growth rate, quality, value, and marketability. More detailed information regarding site

index is available in the “National Forestry Manual,” which is available in local offices of the Natural Resources Conservation Service or on the Internet.

The *volume of wood fiber*, a number, is the yield likely to be produced by the most important tree species. This number, expressed as cubic feet per acre per year and calculated at the age of culmination of the mean annual increment (CMAI), indicates the amount of fiber produced in a fully stocked, even-aged, unmanaged stand.

Trees to manage are those that are preferred for planting, seeding, or natural regeneration and those that remain in the stand after thinning or partial harvest.

Forest Management

In table 8 (Hazard of Erosion and Soil Rutting on Forestland), table 9 (Haul Roads, Log Landings, and Harvest Equipment Operation on Forestland), and table 10 (Seedling Mortality and Windthrow Hazard on Forestland), interpretive ratings are given for various aspects of forest management. The ratings are both verbal and numerical.

Some rating class terms indicate the degree to which the soils are suited to a specified forest management practice. *Well suited* indicates that the soil has features that are favorable for the specified practice and has no limitations. Good performance can be expected, and little or no maintenance is needed. *Moderately suited* indicates that the soil has features that are moderately favorable for the specified practice. One or more soil properties are less than desirable, and fair performance can be expected. Some maintenance is needed. *Poorly suited* indicates that the soil has one or more properties that are unfavorable for the specified practice. Overcoming the unfavorable properties requires special design, extra maintenance, and costly alteration. *Unsuited* indicates that the expected performance of the soil is unacceptable for the specified practice or that extreme measures are needed to overcome the undesirable soil properties.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.01 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the specified forest management practice (1.00) and the point at which the soil feature is not a limitation (0.00).

Rating class terms for seedling mortality and windthrow hazard are expressed as *low, moderate,* and *high*. Where these terms are used, the numerical ratings indicate gradations between the point at which the potential for seedling mortality or windthrow is highest (1.00) and the point at which the potential is lowest (0.00).

The paragraphs that follow indicate the soil properties considered in rating the soils for forest management practices.

For *limitations affecting construction of haul roads*, the ratings are based on slope, flooding, content of sand and clay, rock fragments on the surface, depth to a restrictive layer, depth to a water table, and ponding. The limitations are described as slight, somewhat limited, or very limited. A rating of *slight* indicates that no significant limitations affect construction activities, *somewhat limited* indicates that one or more limitations can cause some difficulty in construction, and *very limited* indicates that one or more limitations can make construction very difficult or very costly.

The ratings of *suitability for log landings* are based on slope, rock fragments on the surface, content of sand and clay, depth to a water table, ponding, flooding, and soil strength. The soils are described as well suited, moderately suited, or poorly suited to use as log landings.

Ratings in the column *suitability for operation of harvesting equipment* are based on slope, rock fragments on the surface, content of sand and clay, soil strength, depth to a water table, and ponding. The soils are described as well suited, moderately suited, or poorly suited to this use.

Ratings in the column *soil rutting hazard* are based on depth to a water table, slope, and soil strength. Ruts form as a result of the operation of forest equipment. The hazard is described as slight, moderate, or severe. A rating of *slight* indicates that the soil is subject to little or no rutting, *moderate* indicates that rutting is likely, and *severe* indicates that ruts form readily.

Ratings in the column *hazard of off-road or off-trail erosion* are based on slope and on soil erodibility factor K. The soil loss is caused by sheet or rill erosion in off-road or off-trail areas where more than 50 percent of the surface has been exposed by logging, grazing, mining, or other kinds of disturbance. The hazard is described as slight, moderate, severe, or very severe. A rating of *slight* indicates that erosion is unlikely under ordinary climatic conditions; *moderate* indicates that some erosion is likely and that erosion-control measures may be needed; *severe* indicates that erosion is very likely and that erosion-control measures, including revegetation of bare areas, are advised; and *very severe* indicates that significant erosion is expected, loss of soil productivity and off-site damage are likely, and erosion-control measures are costly and generally impractical.

Ratings in the column *potential for seedling mortality* are based on flooding, ponding, depth to a water table, and available water capacity. The soils are described as having a slight, moderate, or severe potential for seedling mortality.

Windthrow is the tipping or blowing over of trees during high wind events. Potential for windthrow is greatest where the root zone is shallow due to one or more limiting soil features. Ratings in the column *potential for windthrow* are based on depth to a water table, depth to bedrock, and depth to dense soil material. The soils are described as having a slight, moderate, or severe potential for windthrow.

More detailed information regarding forest productivity and forest management is available in the "National Forestry Manual", which is available in local offices of the Natural Resources Conservation Service or on the Internet.

Recreation

The soils of the survey area are rated in table 11 (Camp Areas, Picnic Areas, and Playgrounds) and table 12 (Paths and Trails, Off-Road Motorcycle Trails, and Golf Fairways) according to limitations that affect their suitability for recreation. The ratings are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect the recreational uses. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.01 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

The ratings in the tables are based on restrictive soil features, such as wetness, slope, texture of the surface layer, and surface stones or boulders. Susceptibility to flooding is considered. Not considered in the ratings, but important in evaluating a site, are the location and accessibility of the area, the size and shape of the area and its scenic quality, vegetation, access to water, potential water impoundment sites, and access to public sewer lines. The capacity of the soil to absorb septic tank effluent and

the ability of the soil to support vegetation also are important. Soils that are subject to flooding are limited for recreational uses by the duration and intensity of flooding and the season when flooding occurs. In planning recreational facilities, onsite assessment of the height, duration, intensity, and frequency of flooding is essential.

The information in table 11 and table 12 can be supplemented by other information in this survey, for example, interpretations for building site development, construction materials, sanitary facilities, and water management.

Camp areas require site preparation, such as shaping and leveling the tent and parking areas, stabilizing roads and intensively used areas, and installing sanitary facilities and utility lines. Camp areas are subject to heavy foot traffic and some vehicular traffic. The ratings are based on the soil properties that affect the ease of developing camp areas and the performance of the areas after development. Slope, stoniness, surface stones or boulders, and depth to bedrock or a cemented pan are the main concerns affecting the development of camp areas. The soil properties that affect the performance of the areas after development are those that influence trafficability and promote the growth of vegetation, especially in heavily used areas. For good trafficability, the surface of camp areas should absorb rainfall readily, remain firm under heavy foot traffic, and not be dusty when dry. The soil properties that influence trafficability are texture of the surface layer, depth to a water table, ponding, flooding, permeability, and large stones. The soil properties that affect the growth of plants are depth to bedrock or a cemented pan, permeability, and toxic substances in the soil.

Picnic areas are subject to heavy foot traffic. Most vehicular traffic is confined to access roads and parking areas. The ratings are based on the soil properties that affect the ease of developing picnic areas and that influence trafficability and the growth of vegetation after development. Slope, stoniness, and surface stones or boulders are the main concerns affecting the development of picnic areas. For good trafficability, the surface of picnic areas should absorb rainfall readily, remain firm under heavy foot traffic, and not be dusty when dry. The soil properties that influence trafficability are texture of the surface layer, depth to a water table, ponding, flooding, permeability, and large stones. The soil properties that affect the growth of plants are depth to bedrock or a cemented pan, permeability, and toxic substances in the soil.

Playgrounds require soils that are nearly level, are free of stones, and can withstand intensive foot traffic. The ratings are based on the soil properties that affect the ease of developing playgrounds and that influence trafficability and the growth of vegetation after development. Slope, stoniness, and surface stones or boulders are the main concerns affecting the development of playgrounds. For good trafficability, the surface of the playgrounds should absorb rainfall readily, remain firm under heavy foot traffic, and not be dusty when dry. The soil properties that influence trafficability are texture of the surface layer, depth to a water table, ponding, flooding, permeability, and large stones. The soil properties that affect the growth of plants are depth to bedrock or a cemented pan, permeability, and toxic substances in the soil.

Paths and trails for hiking and horseback riding should require little or no slope modification through cutting and filling. The ratings are based on the soil properties that affect trafficability and erodibility. These properties are stoniness, depth to a water table, ponding, flooding, slope, surface stones or boulders, and texture of the surface layer.

Off-road motorcycle trails require little or no site preparation. They are not covered with surfacing material or vegetation. Considerable compaction of the soil material is likely. The ratings are based on the soil properties that influence erodibility, trafficability, dustiness, and the ease of revegetation. These properties are stoniness, slope, depth to a water table, ponding, flooding, surface stones or boulders, and texture of the surface layer.

Golf fairways are subject to heavy foot traffic and some light vehicular traffic. Cutting or filling may be required. Irrigation is not considered in the ratings. The ratings are based on the soil properties that affect plant growth and trafficability after vegetation is established, and on maintenance of fairways after construction. The properties that affect plant growth are reaction; depth to a water table; ponding; depth to bedrock or a cemented pan; the available water capacity in the upper 40 inches; the content of salts, sodium, or calcium carbonate; and sulfidic materials. The properties that affect trafficability are flooding, depth to a water table, ponding, slope, stoniness, and the amount of sand, clay, or organic matter in the surface layer. Excessive amounts of surface stones and/or boulders can damage mowing equipment, and drives up construction costs for their removal. The suitability of the soil for traps, tees, roughs, and greens is not considered in the ratings.

Engineering

This section provides information for planning land uses related to urban development and to water management. Soils are rated for various uses, and the most limiting features are identified. Ratings are given for building site development, sanitary facilities, construction materials, and water management. The ratings are based on observed performance of the soils and on the estimated data and test data in the "Soil Properties" section.

Information in this section is intended for land use planning, for evaluating land use alternatives, and for planning site investigations prior to design and construction. The information, however, has limitations. For example, estimates and other data generally apply only to that part of the soil between the surface and a depth of 5 to 7 feet. Because of the map scale, small areas of different soils may be included within the mapped areas of a specific soil.

The information is not site specific and does not eliminate the need for onsite investigation of the soils or for testing and analysis by personnel experienced in the design and construction of engineering works.

Government ordinances and regulations that restrict certain land uses or impose specific design criteria were not considered in preparing the information in this section. Local ordinances and regulations should be considered in planning, in site selection, and in design.

Soil properties, site features, and observed performance were considered in determining the ratings in this section. During the fieldwork for this soil survey, determinations were made about particle-size distribution, liquid limit, plasticity index, soil reaction, depth to bedrock, hardness of bedrock within 5 to 7 feet of the surface, soil wetness, depth to a water table, ponding, slope, likelihood of flooding, natural soil structure aggregation, and soil density. Data were collected about kinds of clay minerals, mineralogy of the sand and silt fractions, and the kinds of adsorbed cations. Estimates were made for erodibility, permeability, corrosivity, shrink-swell potential, available water capacity, and other behavioral characteristics affecting engineering uses.

This information can be used to evaluate the potential of areas for residential, commercial, industrial, and recreational uses; make preliminary estimates of construction conditions; evaluate alternative routes for roads, streets, highways, pipelines, and underground cables; evaluate alternative sites for sanitary landfills, septic tank absorption fields, and sewage lagoons; plan detailed onsite investigations of soils and geology; locate potential sources of gravel, sand, earthfill, and topsoil; plan drainage systems, irrigation systems, ponds, terraces, and other structures for soil and water conservation; and predict performance of proposed small structures and pavements by comparing the performance of existing similar structures on the same or similar soils.

The information in the tables, along with the soil maps, the soil descriptions, and other data provided in this survey, can be used to make additional interpretations.

Some of the terms used in this soil survey have a special meaning in soil science and are defined in the Glossary.

Building Site Development

Soil properties influence the development of building sites, including the selection of the site, the design of the structure, construction, performance after construction, and maintenance. Table 13 and table 14 show the degree and kind of soil limitations that affect dwellings with and without basements, small commercial buildings, local roads and streets, shallow excavations, and lawns and landscaping.

The ratings in the tables are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect building site development. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.01 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

Dwellings are single-family houses of three stories or less. For dwellings without basements, the foundation is assumed to consist of spread footings of reinforced concrete built on undisturbed soil at a depth of 2 feet or at the depth of maximum frost penetration, whichever is deeper. For dwellings with basements, the foundation is assumed to consist of spread footings of reinforced concrete built on undisturbed soil at a depth of about 7 feet (fig. 29). The ratings for dwellings are based on the soil properties that affect the capacity of the soil to support a load without movement and on the properties that affect excavation and construction costs. The properties that affect the load-supporting capacity include depth to a water table, ponding, flooding, subsidence, linear extensibility (shrink-swell potential), and compressibility. Compressibility is inferred from the Unified classification. The properties that affect the ease and amount of excavation include depth to a water table, ponding, flooding, slope, depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, and the amount and size of rock fragments.

Small commercial buildings are structures that are less than three stories high and do not have basements. The foundation is assumed to consist of spread footings of reinforced concrete built on undisturbed soil at a depth of 2 feet or at the depth of maximum frost penetration, whichever is deeper. The ratings are based on the soil properties that affect the capacity of the soil to support a load without movement and on the properties that affect excavation and construction costs. The properties that affect the load-supporting capacity include depth to a water table, ponding, flooding, subsidence, linear extensibility (shrink-swell potential), and compressibility (which is inferred from the Unified classification). The properties that affect the ease and amount of excavation include flooding, depth to a water table, ponding, slope, depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, and the amount and size of rock fragments.

Figure 29.—Excavation for construction of a single family dwelling with a basement in an area of Colonie soils in the town of Crown Point. These somewhat excessively drained sandy soils have no restrictions for construction of dwellings with basements.

Local roads and streets have an all-weather surface and carry automobile and light truck traffic all year. They have a subgrade of cut or fill soil material; a base of gravel, crushed rock, or soil material stabilized by lime or cement; and a surface of flexible material (asphalt), rigid material (concrete), or gravel with a binder. The ratings are based on the soil properties that affect the ease of excavation and grading and the traffic-supporting capacity. The properties that affect the ease of excavation and grading are depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, depth to a water table, ponding, flooding, the amount of large stones, and slope. The properties that affect the traffic-supporting capacity are soil strength (as inferred from the AASHTO group index number), subsidence, linear extensibility (shrink-swell potential), the potential for frost action, depth to a water table, and ponding.

Shallow excavations are trenches or holes dug to a maximum depth of 5 or 6 feet for graves, utility lines, open ditches, or other purposes. The ratings are based on the soil properties that influence the ease of digging and the resistance to sloughing. Depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, the amount of large stones, and dense layers influence the ease of digging, filling, and compacting. Depth to the seasonal high water table, flooding, and ponding may restrict the period when excavations can be made. Slope influences the ease of using machinery. Soil texture, depth to the water table, and linear extensibility (shrink-swell potential) influence the resistance to sloughing.

Lawns and landscaping require soils on which turf and ornamental trees and shrubs can be established and maintained. Irrigation is not considered in the ratings. The ratings are based on the soil properties that affect plant growth and trafficability after vegetation is established. The properties that affect plant growth are reaction; depth to a water table; ponding; depth to bedrock or a cemented pan; the available water capacity in the upper 40 inches; the content of salts, sodium, or calcium carbonate; and sulfidic materials. The properties that affect trafficability are flooding, depth to a

water table, ponding, slope, stoniness, and the amount of sand, clay, or organic matter in the surface layer.

Sanitary Facilities

Table 15 shows the degree and kind of soil limitations that affect septic tank absorption fields. The ratings are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect these uses. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.01 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

Septic tank absorption fields are areas in which effluent from a septic tank is distributed into the soil through perforated pipe or similar devices. That part of the soil between depths of 12 and 48 inches is evaluated. In addition, the bottom layer of soil is evaluated for risk of seepage. The ratings are based on the soil properties that affect absorption of the effluent, construction and maintenance of the system, and public health. Saturated hydraulic conductivity, depth to a water table, ponding, depth to bedrock or dense material, and flooding affect absorption of the effluent. Bedrock, dense material, and stones and boulders interfere with installation. Excessive slope may cause lateral seepage and surfacing of the effluent in downslope areas.

Some soils are underlain by loose sand and gravel or fractured bedrock at a depth of less than 4 feet below the distribution lines. In these soils the absorption field may not adequately filter the effluent, particularly when the system is new. As a result, the ground water may become contaminated.

Construction Materials

Table 16 and table 17 give information about the soils as potential sources of gravel, sand, topsoil, reclamation material, and roadfill. Normal compaction, minor processing, and other standard construction practices are assumed.

Sand and *gravel* are natural aggregates suitable for commercial use with a minimum of processing. They are used in many kinds of construction. Specifications for each use vary widely. In table 16, only the likelihood of finding material in suitable quantity is evaluated. The suitability of the material for specific purposes is not evaluated, nor are factors that affect excavation of the material. The properties used to evaluate the soil as a source of sand or gravel are gradation of grain sizes, the thickness of material, and the content of rock fragments (fig. 30). If the bottom layer of the soil contains sand or gravel, the soil is considered a likely source regardless of thickness. The assumption is that the sand or gravel layer below the depth of observation exceeds the minimum thickness.

The soils are rated *probable* or *improbable* as potential sources of sand and gravel. A rating of *probable* means that the source material is likely to be in or below the soil. The bottom layer and the thickest layer of the soils are assigned numerical ratings. These ratings indicate the likelihood that the layer is a source of sand or gravel. The

Figure 30.—Gravel pit in Howard soils in the town of Ticonderoga. Note the interbedded layers of gravel and sand in this face. Most of the gravel fragments are made up of limestone.

number 0.00 indicates that the layer is not a likely source. A number between 0.00 and 1.00 indicates the degree to which the layer is a likely source.

Hydric soils are associated with wetlands and typically are not considered potential sources of sand or gravel. Soils with a hydric rating of “yes” are assigned a numerical rating of 0.00, regardless of the content of sand or gravel.

The soils are rated *good, fair,* or *poor* as potential sources of topsoil, reclamation material, and roadfill. The features that limit the soils as sources of these materials are specified in the tables. The numerical ratings given after the specified features indicate the degree to which the features limit the soils as sources of topsoil, reclamation material, or roadfill. The lower the number, the greater the limitation.

Topsoil is used to cover an area so that vegetation can be established and maintained. The upper 40 inches of a soil is evaluated for use as topsoil. Also evaluated is the reclamation potential of the borrow area. The ratings are based on the soil properties that affect plant growth; the ease of excavating, loading, and spreading the material; and reclamation of the borrow area. Toxic substances, soil reaction, and the properties that are inferred from soil texture, such as available water capacity and fertility, affect plant growth. The ease of excavating, loading, and spreading is affected by rock fragments, slope, depth to a water table, soil texture, and thickness of suitable material. Reclamation of the borrow area is affected by slope, depth to a water table, rock fragments, depth to bedrock or a cemented pan, and toxic material.

The surface layer of most soils is generally preferred for topsoil because of its organic matter content. Organic matter greatly increases the absorption and retention of moisture and nutrients for plant growth.

Reclamation material is used in areas that have been drastically disturbed by surface mining or similar activities. When these areas are reclaimed, layers of soil material or unconsolidated geological material, or both, are replaced in a vertical sequence. The reconstructed soil favors plant growth. The ratings in the table do not apply to quarries and other mined areas that require an offsite source of reconstruction material. The ratings are based on the soil properties that affect erosion

and stability of the surface and the productive potential of the reconstructed soil. These properties include the content of sodium, salts, and calcium carbonate; reaction; available water capacity; erodibility; texture; content of rock fragments; and content of organic matter and other features that affect fertility.

Roadfill is soil material that is excavated in one place and used in road embankments in another place. In this table, the soils are rated as a source of roadfill for low embankments, generally less than 6 feet high and less exacting in design than higher embankments.

The ratings are for the whole soil, from the surface to a depth of about 5 feet. It is assumed that soil layers will be mixed when the soil material is excavated and spread.

The ratings are based on the amount of suitable material and on soil properties that affect the ease of excavation and the performance of the material after it is in place. The thickness of the suitable material is a major consideration. The ease of excavation is affected by large stones, depth to a water table, and slope. How well the soil performs in place after it has been compacted and drained is determined by its strength (as inferred from the AASHTO classification of the soil) and linear extensibility (shrink-swell potential).

Water Management

Table 18 gives information on the soil properties and site features that affect water management. The degree and kind of soil limitations are given for pond reservoir areas; embankments, dikes, and levees; and aquifer-fed excavated ponds. The ratings are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect these uses. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.01 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

Pond reservoir areas hold water behind a dam or embankment. Soils best suited to this use have low seepage potential in the upper 60 inches. The seepage potential is determined by the permeability of the soil and the depth to fractured bedrock or other permeable material. Excessive slope can affect the storage capacity of the reservoir area.

Embankments, dikes, and levees are raised structures of soil material, generally less than 20 feet high, constructed to impound water or to protect land against overflow. Embankments that have zoned construction (core and shell) are not considered. In this table, the soils are rated as a source of material for embankment fill. The ratings apply to the soil material below the surface layer to a depth of about 5 feet. It is assumed that soil layers will be uniformly mixed and compacted during construction.

The ratings do not indicate the ability of the natural soil to support an embankment. Soil properties to a depth even greater than the height of the embankment can affect performance and safety of the embankment. Generally, deeper onsite investigation is needed to determine these properties.

Soil material in embankments must be resistant to seepage, piping, and erosion and have favorable compaction characteristics. Unfavorable features include less than 5 feet of suitable material and a high content of stones or boulders, organic matter, or salts or sodium. A high water table affects the amount of usable material. It also affects trafficability.

Aquifer-fed excavated ponds are pits or dugouts that extend to a ground-water aquifer or to a depth below a permanent water table. Excluded are ponds that are fed only by surface runoff and embankment ponds that impound water 3 feet or more above the original surface. Excavated ponds are affected by depth to a permanent water table, permeability of the aquifer, and quality of the water as inferred from the salinity of the soil. Depth to bedrock and the content of large stones affect the ease of excavation.

Soil Properties

Data relating to soil properties are collected during the course of the soil survey.

Soil properties are ascertained by field examination of the soils and by laboratory index testing of some benchmark soils. Established standard procedures are followed. During the survey, many shallow borings are made and examined to identify and classify the soils and to delineate them on the soil maps. Samples are taken from some typical profiles and tested in the laboratory to determine particle-size distribution, plasticity, and compaction characteristics. These results are reported in table 19.

Estimates of soil properties are based on field examinations, on laboratory tests of samples from the survey area, and on laboratory tests of samples of similar soils in nearby areas. Tests verify field observations, verify properties that cannot be estimated accurately by field observation, and help to characterize key soils.

The estimates of soil properties are shown in tables. They include engineering index properties, physical and chemical properties, and pertinent soil and water features.

Engineering Index Properties

Table 19 gives the engineering classifications and the range of index properties for the layers of each soil in the survey area.

Depth to the upper and lower boundaries of each layer is indicated.

Texture is given in the standard terms used by the U.S. Department of Agriculture. These terms are defined according to percentages of sand, silt, and clay in the fraction of the soil that is less than 2 millimeters in diameter. "Loam," for example, is soil that is 7 to 27 percent clay, 28 to 50 percent silt, and less than 52 percent sand. If the content of particles coarser than sand is 15 percent or more, an appropriate modifier is added, for example, "gravelly." Textural terms are defined in the Glossary.

Classification of the soils is determined according to the Unified soil classification system (ASTM, 2001) and the system adopted by the American Association of State Highway and Transportation Officials (AASHTO, 2000).

The Unified system classifies soils according to properties that affect their use as construction material. Soils are classified according to particle-size distribution of the fraction less than 3 inches in diameter and according to plasticity index, liquid limit, and organic matter content. Sandy and gravelly soils are identified as GW, GP, GM, GC, SW, SP, SM, and SC; silty and clayey soils as ML, CL, OL, MH, CH, and OH; and highly organic soils as PT. Soils exhibiting engineering properties of two groups can have a dual classification, for example, CL-ML.

The AASHTO system classifies soils according to those properties that affect roadway construction and maintenance. In this system, the fraction of a mineral soil that is less than 3 inches in diameter is classified in one of seven groups from A-1 through A-7 on the basis of particle-size distribution, liquid limit, and plasticity index. Soils in group A-1 are coarse grained and low in content of fines (silt and clay). At the other extreme, soils in group A-7 are fine grained. Highly organic soils are classified in group A-8 on the basis of visual inspection.

If laboratory data are available, the A-1, A-2, and A-7 groups are further classified as A-1-a, A-1-b, A-2-4, A-2-5, A-2-6, A-2-7, A-7-5, or A-7-6. As an additional

refinement, the suitability of a soil as subgrade material can be indicated by a group index number. Group index numbers range from 0 for the best subgrade material to 20 or higher for the poorest. The AASHTO classification for soils tested, with group index numbers in parentheses, is given in table 19.

Rock fragments larger than 10 inches in diameter and 3 to 10 inches in diameter are indicated as a percentage of the total soil on a dry-weight basis. The percentages are estimates determined mainly by converting volume percentage in the field to weight percentage.

Percentage (of soil particles) passing designated sieves is the percentage of the soil fraction less than 3 inches in diameter based on an ovendry weight. The sieves, numbers 4, 10, 40, and 200 (USA Standard Series), have openings of 4.76, 2.00, 0.420, and 0.074 millimeters, respectively. Estimates are based on laboratory tests of soils sampled in the survey area and in nearby areas and on estimates made in the field.

Liquid limit and *plasticity index* (Atterberg limits) indicate the plasticity characteristics of a soil. The estimates are based on test data from the survey area or from nearby areas and on field examination.

The estimates of particle-size distribution, liquid limit, and plasticity index are generally rounded to the nearest 5 percent. Thus, if the ranges of gradation and Atterberg limits extend a marginal amount (1 or 2 percentage points) across classification boundaries, the classification in the marginal zone is generally omitted in the table.

Physical Properties

Table 20 shows estimates of some physical characteristics and features that affect soil behavior. These estimates are given for the layers of each soil in the survey area. The estimates are based on field observations and on test data for these and similar soils.

Depth to the upper and lower boundaries of each layer is indicated.

Particle size is the effective diameter of a soil particle as measured by sedimentation, sieving, or micrometric methods. Particle sizes are expressed as classes with specific effective diameter class limits. The broad classes are sand, silt, and clay, ranging from the larger to the smaller.

Sand as a soil separate consists of mineral soil particles that are 0.05 millimeter to 2 millimeters in diameter. In table 20, the estimated sand content of each soil layer is given as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

Silt as a soil separate consists of mineral soil particles that are 0.002 to 0.05 millimeter in diameter. In table 20, the estimated silt content of each soil layer is given as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

Clay as a soil separate consists of mineral soil particles that are less than 0.002 millimeter in diameter. In table 20, the estimated clay content of each soil layer is given as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

The content of sand, silt, and clay affects the physical behavior of a soil. Particle size is important for engineering and agronomic interpretations, for determination of soil hydrologic qualities, and for soil classification.

The amount and kind of clay affect the fertility and physical condition of the soil and the ability of the soil to adsorb cations and to retain moisture. They influence shrink-swell potential, permeability, plasticity, the ease of soil dispersion, and other soil properties. The amount and kind of clay in a soil also affect tillage and earthmoving operations.

Moist bulk density is the weight of soil (ovendry) per unit volume. Volume is measured when the soil is at field moisture capacity, that is, the moisture content at $^1/_3$- or $^1/_{10}$-bar (33kPa or 10kPa) moisture tension. Weight is determined after the soil is dried at 105 degrees C. In the table, the estimated moist bulk density of each soil horizon is expressed in grams per cubic centimeter of soil material that is less than 2 millimeters in diameter. Bulk density data are used to compute shrink-swell potential, available water capacity, total pore space, and other soil properties. The moist bulk density of a soil indicates the pore space available for water and roots. Depending on soil texture, a bulk density of more than 1.4 can restrict water storage and root penetration. Moist bulk density is influenced by texture, kind of clay, content of organic matter, and soil structure.

Permeability (K_{sat}) refers to the ability of a soil to transmit water or air. The term "permeability," as used in soil surveys, indicates saturated hydraulic conductivity (K_{sat}). The estimates in the table indicate the rate of water movement, in inches per hour, when the soil is saturated. They are based on soil characteristics observed in the field, particularly structure, porosity, and texture. Permeability is considered in the design of soil drainage systems and septic tank absorption fields.

Available water capacity refers to the quantity of water that the soil is capable of storing for use by plants. The capacity for water storage is given in inches of water per inch of soil for each soil layer. The capacity varies, depending on soil properties that affect retention of water. The most important properties are the content of organic matter, soil texture, bulk density, and soil structure. Available water capacity is an important factor in the choice of plants or crops to be grown and in the design and management of irrigation systems. Available water capacity is not an estimate of the quantity of water actually available to plants at any given time.

Linear extensibility refers to the change in length of an unconfined clod as moisture content is decreased from a moist to a dry state. It is an expression of the volume change between the water content of the clod at $^1/_3$- or $^1/_{10}$-bar tension (33kPa or 10kPa tension) and oven dryness. The volume change is reported in the table as percent change for the whole soil. Volume change is influenced by the amount and type of clay minerals in the soil.

Linear extensibility is used to determine the shrink-swell potential of soils. The shrink-swell potential is low if the soil has a linear extensibility of less than 3 percent; moderate if 3 to 6 percent; high if 6 to 9 percent; and very high if more than 9 percent. If the linear extensibility is more than 3, shrinking and swelling can cause damage to buildings, roads, and other structures and to plant roots. Special design commonly is needed.

Organic matter is the plant and animal residue in the soil at various stages of decomposition. In table 20, the estimated content of organic matter is expressed as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

The content of organic matter in a soil can be maintained by returning crop residue to the soil. Organic matter has a positive effect on available water capacity, water infiltration, soil organism activity, and tilth. It is a source of nitrogen and other nutrients for crops and soil organisms.

Erosion factors are shown in table 20 as the K factor (Kw and Kf) and the T factor. Erosion factor K indicates the susceptibility of a soil to sheet and rill erosion by water. Factor K is one of six factors used in the Universal Soil Loss Equation (USLE) and the Revised Universal Soil Loss Equation (RUSLE) to predict the average annual rate of soil loss by sheet and rill erosion in tons per acre per year. The estimates are based primarily on percentage of silt, sand, and organic matter and on soil structure and permeability. Values of K range from 0.02 to 0.69. Other factors being equal, the higher the value, the more susceptible the soil is to sheet and rill erosion by water.

Erosion factor Kw indicates the erodibility of the whole soil. The estimates are modified by the presence of rock fragments.

Erosion factor Kf indicates the erodibility of the fine-earth fraction, or the material less than 2 millimeters in size.

Erosion factor T is an estimate of the maximum average annual rate of soil erosion by wind or water that can occur without affecting crop productivity over a sustained period. The rate is in tons per acre per year.

Wind erodibility groups are made up of soils that have similar properties affecting their susceptibility to wind erosion in cultivated areas. The soils assigned to group 1 are the most susceptible to wind erosion, and those assigned to group 8 are the least susceptible. The groups are as follows:

1. Coarse sands, sands, fine sands, and very fine sands.

2. Loamy coarse sands, loamy sands, loamy fine sands, loamy very fine sands, ash material, and sapric soil material.

3. Coarse sandy loams, sandy loams, fine sandy loams, and very fine sandy loams.

4L. Calcareous loams, silt loams, clay loams, and silty clay loams.

4. Clays, silty clays, noncalcareous clay loams, and silty clay loams that are more than 35 percent clay.

5. Noncalcareous loams and silt loams that are less than 20 percent clay and sandy clay loams, sandy clays, and hemic soil material.

6. Noncalcareous loams and silt loams that are more than 20 percent clay and noncalcareous clay loams that are less than 35 percent clay.

7. Silts, noncalcareous silty clay loams that are less than 35 percent clay, and fibric soil material.

8. Soils that are not subject to wind erosion because of rock fragments on the surface or because of surface wetness.

Wind erodibility index is a numerical value indicating the susceptibility of soil to wind erosion, or the tons per acre per year that can be expected to be lost to wind erosion. There is a close correlation between wind erosion and the texture of the surface layer, the size and durability of surface clods, rock fragments, organic matter, and a calcareous reaction. Soil moisture and frozen soil layers also influence wind erosion.

Chemical Properties

Table 21 shows estimates of some chemical characteristics and features that affect soil behavior. These estimates are given for the layers of each soil in the survey area. The estimates are based on field observations and on test data for these and similar soils.

Depth to the upper and lower boundaries of each layer is indicated.

Cation-exchange capacity is the total amount of extractable bases that can be held by the soil, expressed in terms of milliequivalents per 100 grams of soil at neutrality (pH 7.0) or at some other stated pH value. Soils having a low cation-exchange capacity hold fewer cations and may require more frequent applications of fertilizer than soils having a high cation-exchange capacity. The ability to retain cations reduces the hazard of ground-water pollution.

Effective cation-exchange capacity refers to the sum of extractable bases plus aluminum expressed in terms of milliequivalents per 100 grams of soil. It is determined for soils that have pH of less than 5.5.

Soil reaction is a measure of acidity or alkalinity. The pH of each soil horizon is based on many field tests. For many soils, values have been verified by laboratory analyses. Soil reaction is important in selecting crops and other plants, in evaluating soil amendments for fertility and stabilization, and in determining the risk of corrosion. The reaction for organic horizons is given as CaCl2 based pH and the reaction for mineral soil horizons is given as H2O based pH.

Calcium carbonate equivalent is the percent of carbonates, by weight, in the fraction of the soil less than 2 millimeters in size. The availability of plant nutrients is influenced

by the amount of carbonates in the soil. Incorporating nitrogen fertilizer into calcareous soils helps to prevent nitrite accumulation and ammonium-N volatilization.

Water Features

Table 22 gives estimates of various water features. The estimates are used in land use planning that involves engineering considerations.

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The four hydrologic soil groups are:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas.

The *months* in the table indicate the portion of the year in which the feature is most likely to be a concern.

Water table refers to a saturated zone in the soil. Table 22 indicates, by month, depth to the top (*upper limit*) and base (*lower limit*) of the saturated zone in most years. Estimates of the upper and lower limits are based mainly on observations of the water table at selected sites and on evidence of a saturated zone, namely grayish colors or mottles (redoximorphic features) in the soil. A saturated zone that lasts for less than a month is not considered a water table.

Ponding is standing water in a closed depression. Unless a drainage system is installed, the water is removed only by percolation, transpiration, or evaporation. Table 22 indicates *surface water depth* and the *duration* and *frequency* of ponding. Duration is expressed as *very brief* if less than 2 days, *brief* if 2 to 7 days, *long* if 7 to 30 days, and *very long* if more than 30 days. Frequency is expressed as none, rare, occasional, and frequent. *None* means that ponding is not probable; *rare* that it is unlikely but possible under unusual weather conditions (the chance of ponding is nearly 0 percent to 5 percent in any year); *occasional* that it occurs, on the average, once or less in 2 years (the chance of ponding is 5 to 50 percent in any year); and *frequent* that it occurs, on the average, more than once in 2 years (the chance of ponding is more than 50 percent in any year).

Flooding is the temporary inundation of an area caused by overflowing streams, by runoff from adjacent slopes, or by tides. Water standing for short periods after rainfall or snowmelt is not considered flooding, and water standing in swamps and marshes is considered ponding rather than flooding.

Duration and *frequency* are estimated. Duration is expressed as *extremely brief* if 0.1 hour to 4 hours, *very brief* if 4 hours to 2 days, *brief* if 2 to 7 days, *long* if 7 to 30 days, and *very long* if more than 30 days. Frequency is expressed as none, very rare, rare, occasional, frequent, and very frequent. *None* means that flooding is not probable; *very rare* that it is very unlikely but possible under extremely unusual weather conditions (the chance of flooding is less than 1 percent in any year); *rare* that it is unlikely but possible under unusual weather conditions (the chance of flooding is 1 to 5 percent in any year); *occasional* that it occurs infrequently under normal weather conditions (the chance of flooding is 5 to 50 percent in any year); *frequent* that it is likely to occur often under normal weather conditions (the chance of flooding is more than 50 percent in any year but is less than 50 percent in all months in any year); and *very frequent* that it is likely to occur very often under normal weather conditions (the chance of flooding is more than 50 percent in all months of any year).

The information is based on evidence in the soil profile, namely thin strata of gravel, sand, silt, or clay deposited by floodwater; irregular decrease in organic matter content with increasing depth; and little or no horizon development.

Also considered are local information about the extent and levels of

flooding and the relation of each soil on the landscape to historic floods. Information on the extent of flooding based on soil data is less specific than that provided by detailed engineering surveys that delineate flood-prone areas at specific flood frequency levels.

Soil Features

Table 23 gives estimates of various soil features. The estimates are used in land use planning that involves engineering considerations.

A *restrictive layer* is a nearly continuous layer that has one or more physical, chemical, or thermal properties that significantly impede the movement of water and air through the soil or that restrict roots or otherwise provide an unfavorable root environment. Examples are bedrock, cemented layers, dense layers, and frozen layers. The table indicates the hardness and thickness of the restrictive layer, both of which significantly affect the ease of excavation. *Depth to top* is the vertical distance from the soil surface to the upper boundary of the restrictive layer.

Subsidence is the settlement of organic soils or of saturated mineral soils of very low density. Subsidence generally results from either desiccation and shrinkage or oxidation of organic material, or both, following drainage. Subsidence takes place gradually, usually over a period of several years. The table shows the expected initial subsidence, which usually is a result of drainage, and total subsidence, which results from a combination of factors.

Potential for frost action is the likelihood of upward or lateral expansion of the soil caused by the formation of segregated ice lenses (frost heave) and the subsequent collapse of the soil and loss of strength on thawing. Frost action occurs when moisture moves into the freezing zone of the soil. Temperature, texture, density, permeability, content of organic matter, and depth to the water table are the most important factors considered in evaluating the potential for frost action. It is assumed that the soil is not insulated by vegetation or snow and is not artificially drained. Silty and highly structured, clayey soils that have a high water table in winter are the most susceptible to frost action. Well drained, very gravelly, or very sandy soils are the least susceptible. Frost heave and low soil strength during thawing cause damage to pavements and other rigid structures.

Risk of corrosion pertains to potential soil-induced electrochemical or chemical action that corrodes or weakens uncoated steel or concrete. The rate of corrosion of uncoated steel is related to such factors as soil moisture, particle-size distribution, acidity, and electrical conductivity of the soil. The rate of corrosion of concrete is based

mainly on the sulfate and sodium content, texture, moisture content, and acidity of the soil. Special site examination and design may be needed if the combination of factors results in a severe hazard of corrosion. The steel or concrete in installations that intersect soil boundaries or soil layers is more susceptible to corrosion than the steel or concrete in installations that are entirely within one kind of soil or within one soil layer.

For uncoated steel, the risk of corrosion, expressed as *low, moderate,* or *high,* is based on soil drainage class, total acidity, electrical resistivity near field capacity, and electrical conductivity of the saturation extract.

For concrete, the risk of corrosion also is expressed as *low, moderate,* or *high*. It is based on soil texture, acidity, and amount of sulfates in the saturation extract.

Engineering Index Test Data

Table 24 shows laboratory test data for several pedons sampled at carefully selected sites in the survey area. The pedons are representative of the series described in the section “Soil Series and Their Morphology.” The soil samples were tested by the New York State Department of Transportation, Bureau of Soil Mechanics. The testing methods generally are those of the American Association of State Highway and Transportation Officials (AASHTO) or the American Society for Testing and Materials (ASTM).

The tests and methods are AASHTO classification—M 145 (AASHTO), D 3282 (ASTM); Unified classification—D 2487 (ASTM); Mechanical analysis—T 88 (AASHTO), D 422 (ASTM), D 2217 (ASTM); Liquid limit—T 89 (AASHTO), D 4318 (ASTM); Plasticity index—T 90 (AASHTO), D 4318 (ASTM); Moisture density T 99 (AASHTO), D 698 (ASTM); Specific gravity—T 100 (AASHTO), D 854 (ASTM); California bearing ratio—T 193 (AASHTO), D 1883 (ASTM); and Shrinkage—T 92 (AASHTO), D 427 (ASTM).

Relationship between Parent Material, Landscape Position, and Drainage Class of the Soils

Table 25 shows the relationship between some of the factors that have influenced the development and morphology of the soils in Essex County. The soils are grouped according to the type of landscape positions on which they occur. These landscape positions include glaciated uplands, outwash plains, lacustrine plains and deltas, flood plains, and swamps and bogs. The soils that are on the similar landscapes are grouped according to their depth over bedrock. The soils are also grouped by texture and by morphology of the parent material in which they formed. Finally, the soils are grouped by drainage class. Soils that have the same parent material, soil depth, and landscape position, but are in a different drainage class form a soil catena. Nellis, Amenia, Massena, and Sun soils are examples of soils that form a catena in Essex County. A few components, which are classified above the series level, are less narrowly defined and may cover more than one drainage class such as Udorthents, Udifluvents, and Fluvaquents. The information in Table 26 establishes general relationships among the soils in the county. It supplements the information provided in the section “Formation of the Soils.” Detailed information on the morphology and characteristics of each soil is provided in the section “Taxonomic Units and Their Morphology.”

Engineering Properties of Geologic Deposits

The geologic deposits that occur in Essex County include till, outwash, delta deposits, beach ridge deposits, lacustrine and marine deposits, alluvium, and organic

deposits. The engineering significance of each geologic deposit is influenced to a great extent by its mode of deposition which, in turn, determines the texture of the material and the internal structure of the landform. Other influences are the position of the deposit on the landscape and depth of the water table.

In Essex County, the geologic deposits are divided into the following categories: deep till deposits; shallow or moderately deep to bedrock deposits; stratified, coarse textured deposits; stratified, fine textured deposits; and organic deposits. These deposits are described in the following paragraphs.

Deep till deposits—Deep till deposits are unstratified, highly variable mixtures of all particle sizes ranging from rock fragment to clay. This material was scoured and transported from nearby sources by glacial ice and was deposited as ground moraines, lateral moraines, or recessional moraines. Bedrock is usually greater than five feet deep. Individual rock fragments in the soil generally reflect the local bedrock type.

Soils that formed in deep till deposits include Adirondack, Amenia, Ampersand, Becket, Bombay, Charlton, Esther, Fernlake, Georgia, Hermon, Kalurah, Malone, Massena, Monadnock, Mundalite, Nellis, Pittsfield, Pyrities, Skerry, Sun, Sunapee, Tahawus, and Wilmington series. Cayuga and Churchville soils have a veneer of fine textured lacustrine or marine clay material over deep till.

Most of the deep till deposits have been subjected to the compacting weight of overriding ice (lodgment till). A few of these soils formed in meltout or ablation till deposited at the fringe of the glacier or at the base of stagnating ice. Slopes range from gently sloping to very steep, and the characteristics of these landscapes are such that cut and fill earthwork is needed in most construction. Both types of tills commonly provide stable, relatively incompressible foundations for engineering works; however, ablation tills are generally more friable and have better internal drainage. Fill material from these deposits, when properly compacted, generally provides stable embankments. Steep cut slopes commonly are subject to surface sloughing and erosion. Poorly drained and very poorly drained tills on toeslopes are subject to surface saturation and accumulation of organic deposits (muck or peat).

Very shallow, shallow, or moderately deep to bedrock deposits—These deposits consist of unstratified glacially transported materials deposited as a thin veneer over bedrock, or slightly to highly decomposed plant material accumulating as an organic mat on the bedrock surface due to cool climatic conditions. The soil material commonly is 0.5 foot to 3.0 feet thick, and rock outcrop is common in some areas. The landforms and topography generally are controlled by the bedrock.

Soils that formed in till over metamorphosed igneous bedrock include Chatfield, Couchsachraga, Hogback, Hollis, Lyman, Rawsonville, Santanoni, Skylight, Tunbridge, and Wallface soils. Farmington and Galway soils formed in till over limestone bedrock. Nehasne soils formed in till over marble bedrock. Knob Lock and Ricker soils formed in organic material usually over metamorphosed igneous bedrock.

The main engineering concerns are those that relate to the underlying bedrock which is generally massive and hard, and ground water found in the fracture systems of the bedrock. The overlying material has engineering characteristics similar to the deep tills described above, or the organic deposits described below. It is limited in quantity as a source of fill material because of its thickness over bedrock.

Stratified coarse textured deposits—Materials dominated by gravel and sand sorted by glacial meltwater into layered or stratified deposits are included in this category, as well as coarser-textured material deposited by fluvial action. They occupy such geologic landforms as outwash plains and terraces, kame terraces, beach ridges, deltas, and the coarser portions of alluvial fans and flood plains. The strata within these deposits may be well sorted or poorly sorted, and range in particle size from cobbles to silt. The deposits commonly are loose and porous, and have moderately rapid or rapid permeability.

Soils that formed on gravelly outwash plains, kame terraces, and beach ridges include Colton, Duxbury, and Howard soils. Soils that formed in sandy deltaic and beach deposits are Adams, Champlain, Colonie, Croghan, Deerfield, Factoryville, Gougeville, Mooers, Naumburg, Searsport, Stafford, and Windsor soils. Claverack and Cosad soils are moderately deep sandy beach and deltaic deposits overlying lacustrine or marine clay.

Coarse-textured deposits generally have relatively high strength and low compressibility. Because of their loose and porous nature, most of these deposits are not highly erodible. They are subject to settlement when vibrated.

These deposits of gravel and sand have many uses as construction material. Their uses depend primarily on gradation, soundness, and plasticity. They are sources of sand and gravel for general use, and they may be used as fill material for highway embankments, in parking areas and other developments, and on construction sites where this material is needed to reduce stress on the underlying soils. They may also be used as sub-base for pavements; wearing surfaces for driveways, parking lots, and some roads; material for highway shoulders; and free drainage backfill for structures and pipes. In addition, they may be used to form outside shells of dams for impounding water and as slope protection blankets to drain and help stabilize wet, cut slopes.

Stratified, fine textured deposits—Deposits in this category consist of fine textured sediment transported by glacial meltwater and deposited in quiet proglacial lakes or ancient estuaries, and recent alluvium or flood plain deposits. Clayey marine deposits include Covington, Kingsbury, Livingston, and Vergennes soils. Elmridge soils consist of loamy deltaic or beach material overlying marine clay. Silty clay lacustrine deposits include Collamer, Depeyster, Dunkirk, Hailesboro, Niagara, and Wegatchie soils. Silty and very fine sand lacustrine deposits include Hartland, Nicholville, Roundabout, and Tonawanda soils. Loamy alluvial soils include Occum, Ondawa, Podunk, Pootatuck, Rippowam, and Rumney soils. Silty alluvial soils include Charles, Cornish, Lovewell, and Medomak soils. Recent alluvial deposits are in some cases underlain by coarse-textured sandy and gravelly material.

Due to their fine-texture and high moisture content, the more clayey deposits have low strengths, are compressible, and may settle for long periods of time under a superimposed load. Also, the marine clays may exhibit high shrink-swell behavior, and are susceptible to slope failure such as rotational slump in dissected areas. The soils with a higher fine sand and silt content have low compressibility, but are highly erodible and frost susceptible. Recent alluvial soils are subject to occasional to frequent flooding of brief duration.

Saturation generally increases the instability of these soils.

The fine-textured deposits are difficult to use for engineering works, especially in areas that are flat and poorly drained. Sites for embankments and heavy structures or buildings on all soils formed in these finer-textured sediments must be investigated for strength and settlement characteristics, and for the effects of ground water.

Organic deposits—Organic deposits consist mainly of accumulations of plant remains. In some places they are underlain by mineral soil material within four feet of the surface. These deposits occur in very poorly drained low-lying areas, in bogs or swamps that are covered with water during most of the year, and in freshwater marsh areas.

Soils formed in saturated organic material include Bucksport, Burnt Vly, Catden, Pleasant Lake, Whallonsburg, and Wonsqueak soils.

The soils that formed in organic deposits are entirely unsuitable for foundations for engineering work because they are wet, weak, and highly compressible. Generally, the organic material should be removed to a depth where there is suitable underlying material, and should be replaced with suitable backfill. Placing fill material over organic deposits results in long-term settlement.

Classification of the Soils

The system of soil classification used by the National Cooperative Soil Survey has six categories (Soil Survey Staff, 1998 and 1999). Beginning with the broadest, these categories are the order, suborder, great group, subgroup, family, and series. Classification is based on soil properties observed in the field or inferred from those observations or from laboratory measurements. Table 26 shows the classification of the soils in the survey area. The categories are defined in the following paragraphs.

ORDER. Twelve soil orders are recognized. The differences among orders reflect the dominant soil-forming processes and the degree of soil formation. Each order is identified by a word ending in *sol*. An example is Alfisol.

SUBORDER. Each order is divided into suborders primarily on the basis of properties that influence soil genesis and are important to plant growth or properties that reflect the most important variables within the orders. The last syllable in the name of a suborder indicates the order. An example is Udalf (*Ud*, meaning humid, plus *alf*, from Alfisol).

GREAT GROUP. Each suborder is divided into great groups on the basis of close similarities in kind, arrangement, and degree of development of pedogenic horizons; soil moisture and temperature regimes; type of saturation; and base status. Each great group is identified by the name of a suborder and by a prefix that indicates a property of the soil. An example is Hapludalfs (*Hapl*, meaning minimal horizonation, plus *udalf*, the suborder of the Alfisols that has a udic moisture regime).

SUBGROUP. Each great group has a typic subgroup. Other subgroups are intergrades or extragrades. The typic subgroup is the central concept of the great group; it is not necessarily the most extensive. Intergrades are transitions to other orders, suborders, or great groups. Extragrades have some properties that are not representative of the great group but do not indicate transitions to any other taxonomic class. Each subgroup is identified by one or more adjectives preceding the name of the great group. The adjective *Typic* identifies the subgroup that typifies the great group. An example is Typic Hapludalfs.

FAMILY. Families are established within a subgroup on the basis of physical and chemical properties and other characteristics that affect management. Generally, the properties are those of horizons below plow depth where there is much biological activity. Among the properties and characteristics considered are particle-size class, mineralogy class, cation-exchange activity class, soil temperature regime, soil depth, and reaction class. A family name consists of the name of a subgroup preceded by terms that indicate soil properties. An example is fine-loamy, mixed, active, mesic Typic Hapludalfs.

SERIES. The series consists of soils within a family that have horizons similar in color, texture, structure, reaction, consistence, mineral and chemical composition, and arrangement in the profile.

Soil Series and Their Morphology

In this section, each soil series recognized in the survey area is described. Characteristics of the soil and the material in which it formed are identified for each series. A pedon, a small three-dimensional area of soil that is typical of the series in

the survey area, is described. The detailed description of each soil horizon follows standards in the “Soil Survey Manual” (Soil Survey Division Staff, 1993). Many of the technical terms used in the descriptions are defined in “Soil Taxonomy” (Soil Survey Staff, 1999) and in “Keys to Soil Taxonomy” (Soil Survey Staff, 1998). Unless otherwise indicated, colors in the descriptions are for moist soil. Following the pedon description is the range of important characteristics of the soils in the series.

Adams Series

The Adams series consists of very deep, somewhat excessively drained soils on deltas, kame terraces, outwash plains, outwash terraces, and high stream terraces in the Adirondack Upland. Adams soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 70 percent.

Adams soils are associated on the landscape with Croghan, Naumburg, Searsport, Colton, Duxbury, Burnt Vly, Monadnock, and Tunbridge soils. Croghan soils are moderately well drained. Naumburg soils are somewhat poorly drained. Searsport soils are very poorly drained. Colton soils are gravelly. Duxbury soils are loamy over gravelly. Burnt Vly soils are mucky and very poorly drained. Monadnock soils are loamy over sandy or gravelly, and are well drained. Tunbridge soils are loamy, well drained, and moderately deep to bedrock.

Typical pedon of Adams sand, in a map unit of Monadnock-Adams-Colton complex, 3 to 15 percent slopes, bouldery, at edge of a small clearing in woodland, in the town of Lewis, 3 miles due west of the junction of Hale Hill Road and US Route 9, at an old clearing called “Seven Kiln”; USGS Ausable Forks 15 minute topographic quadrangle, NAD 1927; lat. 44 degrees 20 minutes 02 seconds N. and long. 73 degrees 36 minutes 20 seconds W.

Oe—0 to 2 inches, very dark gray (5YR 3/1) moderately decomposed (hemic) plant material, 40 percent fiber unrubbed, 15 percent rubbed; weak medium granular structure; very friable; many fine and very fine and few medium roots; less than 1 percent rock fragments; strongly acid; clear smooth boundary.

Oa—2 to 4 inches, black (5YR 2/1) highly decomposed (sapric) plant material, 10 percent fiber unrubbed, 2 percent rubbed; weak medium granular structure; very friable; many fine and very fine and few medium roots; less than 1 percent rock fragments; very strongly acid; clear smooth boundary.

E—4 to 5 inches, reddish gray (5YR 5/2) sand; weak fine granular structure; very friable; many fine and very fine, and few medium roots; less than 1 percent rock fragments; very strongly acid; clear smooth boundary.

Bhs—5 to 8 inches, dark reddish brown (5YR 3/3) loamy sand; weak fine granular structure; very friable; common fine and very fine, and few medium and coarse roots; less than 1 percent rock fragments; strongly acid; clear wavy boundary.

Bs—8 to 14 inches, reddish brown (5YR 4/4) loamy sand; weak medium subangular blocky structure; very friable; common fine and very fine, and few medium and coarse roots; less than 1 percent rock fragments; strongly acid; clear smooth boundary.

BC—14 to 23 inches, yellowish brown (10YR 5/6) sand; single grain; loose; few fine, medium, and coarse roots; less than 1 percent rock fragments; moderately acid; clear smooth boundary.

C—23 to 72 inches, light olive brown (2.5Y 5/4) sand; single grain; loose; few fine and medium roots; less than 1 percent rock fragments; moderately acid.

The thickness of the solum ranges from 41 to 89 centimeters. Depth to bedrock is more than 183 centimeters. Rock fragments, mostly gravel, range from 0 to 10 percent above a depth of 51 centimeters and, from 0 to 20 percent below 51 centimeters. Some pedons have contrasting very gravelly deposits below a depth of 100 centimeters.

The sand fraction is dominantly medium and fine. Adams soils are dry for less than 20 consecutive days following the summer solstice and moist within 91 centimeters of the soil surface during the month of August in normal years.

The 0 horizon, where present, is neutral or has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 0 to 3.

Some pedons have an A or Ap horizon that has hue of 5YR to 10YR, value of 2 to 5, and chroma of 1 to 4. Texture is loamy fine sand, loamy sand, fine sand, or sand. Structure is weak or moderate fine or medium granular or it is single-grain. Consistence is friable or very friable. Unless limed, reaction is extremely acid to moderately acid.

The E horizon, where present, has hue of 5YR to 10YR, value of 5 to 7, and chroma of 1 to 3. Texture is loamy fine sand, loamy sand, fine sand, or sand. Structure is granular or weak subangular blocky in some pedons, but most pedons are single-grain. Consistence is friable to loose. Reaction is extremely acid to moderately acid.

The Bhs or Bh horizon, where present, has hue of 2.5YR to 7.5YR, value of 2 or 3, and chroma of 1 to 4. Texture is loamy fine sand, loamy sand, fine sand, or sand. Structure is weak or moderate fine or medium granular or weak subangular blocky, or the horizon is single-grained or massive. Consistence is very friable or friable. Massive, cemented bodies, 1 to 20 centimeters across, range from 0 to 30 percent of the exposed surface area of the horizon. Reaction is very strongly acid to moderately acid.

The Bs horizon has hue of 5YR to 10YR, value of 3 to 6, and chroma of 3 to 8. Texture is loamy fine sand, loamy sand, fine sand, or sand in the fine-earth fraction. Structure is weak granular or subangular blocky, or the horizon is single-grain or massive. Consistence is very friable or loose. Massive, cemented bodies range from 0 to 30 percent of the exposed surface area of the Bs horizon. Reaction is very strongly acid to moderately acid.

The BC horizon has hue of 7.5YR to 5Y, value of 4 to 6, and chroma of 2 to 6. The texture is fine sand to coarse sand in the fine-earth fraction. Some pedons have texture of loamy sand. Consistence is very friable or loose. Cemented bodies range up to 20 percent of the exposed surface area in some pedons. Reaction is very strongly acid to moderately acid.

The C horizon has hue of 5YR to 5Y, value of 4 to 7, and chroma of 2 to 6. Texture is fine sand to coarse sand in the fine-earth fraction. Reaction is very strongly acid to slightly acid.

Adirondack Series

The Adirondack series consists of very deep, somewhat poorly drained soils in shallow depressions on footslopes, and along drainage ways on till plains in uplands and mountainous areas. Adirondack soils formed in loamy sediments underlain by compact, sandy or loamy, very firm lodgment till. Slopes range from 0 to 15 percent.

Adirondack soils are commonly associated with the well drained Becket, Monadnock, and the moderately well drained Skerry and Sunapee soils that are on higher topographic positions. Also associated are the very poorly drained Tahawus soils that have more friable substratums.

Typical pedon of Adirondack fine sandy loam, in a map unit of Adirondack-Sabattis-Tughill complex, 0 to 8 percent slopes, very bouldery, in Hamilton County, New York, town of Morehouse, 100 feet south of a point on NYS Rt 8 where the trail starts to the Fort Noble fire tower; USGS Ohio, NY 15 minute topographic quadrangle; NAD 1927; lat. 43 degrees 23 minutes 36 seconds N. and long. 74 degrees 49 minutes 43 seconds W.

Oe—0 to 2 inches; black (5YR 2.5/1) moderately decomposed (hemic) plant material; (unrubbed 75 percent fibers, rubbed 35 percent fibers;) weak fine and medium

granular structure; very friable; many fine and few medium and coarse roots; extremely acid; clear smooth boundary.

Oa—2 to 4 inches; black (5YR 2.5/1) highly decomposed (sapric) plant material; (unrubbed 25 percent fibers; rubbed 3 percent fibers); moderate fine and medium granular structure; very friable; many fine, few medium and coarse roots; extremely acid; clear smooth boundary.

E—4 to 6 inches; light brownish gray (10YR 6/2 fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine, few medium and coarse roots; 5 percent rock fragments, 1 percent greater than 3 inches; few medium prominent dark reddish brown (5YR 3/4) areas of iron accumulation; very strongly acid; abrupt wavy boundary.

Bh—6 to 8 inches; dark reddish brown (5YR 3/2) fine sandy loam; moderate fine and medium subangular blocky structure; friable with 25 percent firm masses; common fine roots; 5 percent rock fragments, 1 percent greater than 3 inches; common medium and coarse distinct dark reddish brown (5YR 3/4) areas of iron accumulation; very strongly acid; abrupt wavy boundary.

Bhs—8 to 9 inches; dark reddish brown (5YR 3/3) fine sandy loam; weak thin and medium platy structure; friable with 20 percent firm masses; few fine roots; 5 percent rock fragments, 1 percent greater than 3 inches; common medium distinct reddish brown (5YR 4/4) areas of iron accumulation; common medium faint, dark reddish brown (5YR 2/2) iron nodules (ortstein like); very strongly acid; clear wavy boundary.

Bs—9 to 18 inches; brown (7.5YR 5/4-4/4) fine sandy loam; weak thin and medium platy structure parting to weak very fine subangular blocky; friable, with 20 percent firm masses; few fine roots in the upper part; 5 percent rock fragments; 1 percent greater than 3 inches; many medium and coarse distinct yellowish red (5YR 4/6) and common fine faint light brown (7.5YR 6/4) areas of iron accumulation; strongly acid; clear wavy boundary.

BC—18 to 26 inches; yellowish brown (10YR 5/4) to dark yellowish brown (10YR 4/4) sandy loam; weak medium and coarse subangular blocky structure; friable; 10 percent rock fragments, 1 percent greater than 3 inches; many medium and coarse prominent yellowish red (5YR 4/6), common fine and medium faint yellowish brown (10YR 5/6) areas of iron accumulation, few medium faint pale brown (10YR 6/3) areas of iron depletion; strongly acid; gradual wavy boundary.

Cd1—26 to 34 inches; brown (10YR 4/3) gravelly loamy sand; massive with weak medium plate-like divisions; firm; 15 percent rock fragments, 1 percent greater than 3 inches; strongly acid. gradual wavy boundary.

Cd2—34 to 43 inches; grayish brown to brown (10YR 5/2-5/3) gravelly loamy sand; massive; firm in place; 25 percent rock fragments; 3 percent greater than 3 inches; few fine and medium distinct yellowish brown (10YR 5/6) mottles; strongly acid; gradual wavy boundary.

Cd3—43 to 72 inches; grayish brown (2.5Y 5/2) gravelly loamy sand; massive; firm in place, friable when removed; 30 percent rock fragments, 5 percent greater than 3 inches; strongly acid.

The mineral solum thickness ranges from 20 to 38 inches. Depth to bedrock is greater than 60 inches. Redoximorphic features consisting of iron depletions or concentrations occur in the spodic horizon within 20 inches of the mineral soil surface. Rock fragments, mainly stones, cobbles, and gravel, range from 5 to 35 percent, by volume, throughout the mineral soil.

The O horizon ranges from slightly decomposed to highly decomposed plant material. Reaction is extremely acid or very strongly acid.

Some pedons have an A horizon that is neutral or has hue of 5YR to 10YR, value of 1 to 3, and chroma of 0 to 3. Some pedons have an Ap horizon that has hue of 5YR

to 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is sandy loam, fine sandy loam, very fine sandy loam, loam or silt loam in the fine-earth fraction. Reaction ranges from extremely acid to strongly acid. Thickness of the A or Ap horizon is 0 to 8 inches.

The E horizon has hue of 5YR to 10YR, value of 5 to 7, and chroma of 1 or 2. Texture is loamy fine sand, sandy loam, fine sandy loam, loam, or silt loam in the fine-earth fraction. Reaction ranges from extremely acid to strongly acid.

The Bh horizon has hue of 5YR or 7.5YR, value of 2 or 3, and chroma of 1 or 2. Texture is sandy loam, fine sandy loam, loam, or silt loam in the fine-earth fraction. Consistence is friable or very friable, but up to 25 percent firm areas may be present. Reaction ranges from extremely acid to strongly acid.

The Bhs horizon has hue of 5YR or 7.5YR, with value and chroma of 3. Texture, consistence and reaction are similar to the Bh horizon.

The Bs horizon has hue of 5YR or 7.5YR, value of 3 to 5, and chroma of 3 or 4. Texture is sandy loam, fine sandy loam, loam or silt loam in the fine-earth fraction. Consistence is friable or very friable. Reaction ranges from extremely acid to strongly acid.

The BC horizon has hue of 7.5YR to 2.5Y, value of 3 to 6, and chroma of 1 to 4. Texture is loamy fine sand to silt loam in the fine earth fraction. Consistence is friable or firm. Reaction is very strongly acid to moderately acid.

The Cd horizon has hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 1 to 3. Texture is loamy sand, loamy fine sand, coarse sandy loam, sandy loam, fine sandy loam, or loam. It is massive or has plate-like divisions. Consistence is firm or very firm. Vertical desiccation cracks 20 inches or more apart are in some pedons. Reaction is strongly acid or moderately acid. Some pedons have a thin C horizon above the Cd horizon.

Amenia Series

The Amenia series consists of very deep, moderately well drained soils on summits, shoulders, and backslopes of glaciated ridges and on till plains in the Champlain Valley. Amenia soils formed in loamy sediments underlain by firm, loamy, calcareous lodgment till. Slopes range from 2 to 15 percent (fig. 31).

Amenia soils are associated on the landscape with Nellis, Massena, Sun, Bombay, Kingsbury, Churchville, and Howard soils. Nellis soils are well drained. Massena soils are somewhat poorly drained. Sun soils are poorly drained. Bombay soils have higher clay content in the subsoil. Kingsbury soils are clayey and are somewhat poorly drained. Churchville soils are clayey over loamy and are somewhat poorly drained. Howard soils are gravelly and are well drained to excessively drained.

Typical pedon of Amenia fine sandy loam, 2 to 8 percent slopes, in the town of Essex, 500 feet south of junction of Clark Road and Cross Road, 100 feet east of road, in a hay field; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 15 minutes 47 seconds N., and long. 73 degrees 23 minutes 05 seconds W.

Ap—0 to 9 inches, dark brown (10YR 3/3) fine sandy loam; pale brown (10YR 6/3) dry; weak fine and medium granular structure; very friable; many fine roots; 4 percent rock fragments; neutral; clear smooth boundary.

Bw—9 to 14 inches, 60 percent pale brown (10YR 6/3) and 40 percent yellowish brown (7.5YR 4/6) fine sandy loam; moderate fine and medium subangular blocky structure; friable; common fine and few medium roots; 4 percent rock fragments; common fine and medium distinct strong brown (7.5YR 5/6) and (7.5YR 4/6) soft masses of iron accumulation; neutral; clear wavy boundary.

BC—14 to 21 inches, variegated yellowish brown (10YR 5/4) and dark brown (10YR 4/3) fine sandy loam; weak coarse platy structure; friable; few fine roots; common fine and medium tubular and many fine vesicular pores; 4 percent rock fragments, 1 percent greater than 3 inches; few medium dark brown (7.5YR 3/4) ironstone

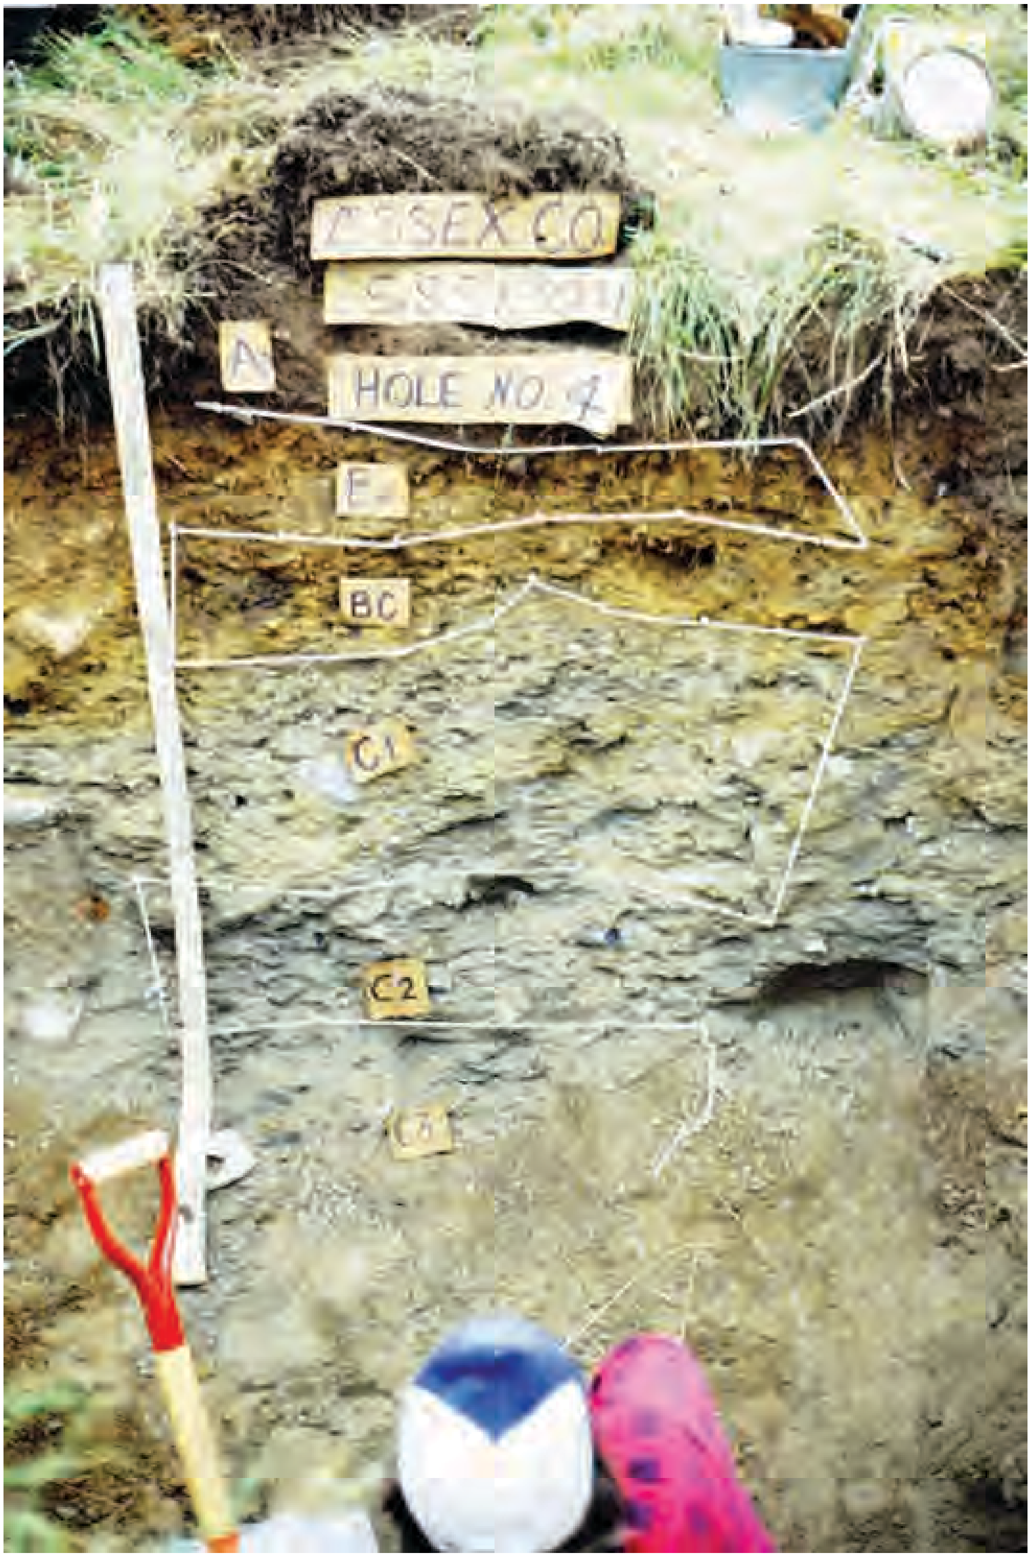

Figure 31.—Soil profile of the Amenia series from a backhoe test pit, in the town of Essex, in a hay field. The gray substratum (C horizons) is a very firm, dense, calcareous till derived mostly from limestone.

nodules; common fine and medium distinct light brownish gray (10YR 6/2) iron depletions in lower part; neutral; clear wavy boundary.

Cd1—21 to 36 inches, 70 percent grayish brown (2.5Y 5/2) and 30 percent yellowish brown (10YR 5/4) fine sandy loam; massive with strong thick and medium plate-like divisions; firm; few fine tubular and common fine vesicular pores; 11 percent rock fragments with 3 percent greater than 3 inches; 10 percent of ped surfaces have coatings of very pale brown (10YR 8/2) calcium carbonate accumulations; few fine faint light brownish gray (10YR 6/2) iron depletions; moderately alkaline, alkaline, violently effervescent; clear wavy boundary.

Cd2—36 to 48 inches, grayish brown (2.5Y 5/2) fine sandy loam; massive with weak thick and medium plate-like divisions; firm; few fine vesicular and tubular pores; 9 percent rock fragments with 3 percent greater than 3 inches; strongly alkaline, alkaline, violently effervescent; gradual wavy boundary.

Cd3—48 to 72 inches, grayish brown (2.5Y 5/2) fine sandy loam; massive; firm; 9 percent rock fragments with 3 percent greater than 3 inches; strongly alkaline, violently effervescent.

The thickness of the solum ranges from 18 to 36 inches and depth to carbonates range from 10 to 34 inches. The carbonates are nearly all of calcium. Depth to bedrock is more than 60 inches. Rock fragments range from 4 to 35 percent by volume throughout the soil.

Undisturbed pedons have A horizons 4 to 7 inches thick. The A horizon has hue of 10YR, value of 2 or 3, and chroma of 2.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 or 4 and chroma of 2 or 3. Texture is silt loam, loam, or fine sandy loam in the fine earth fraction. Structure is weak or moderate granular and consistence is friable or very friable. Reaction ranges from moderately acid to slightly alkaline.

Some pedons have an A/B or AB horizon up to 6 inches thick.
